**Abstract**

We studied the seasonal occurrence of the eriophyid mites in the domatia of *Cinnamomum camphora* leaves and the predatory mite, *Amblyseius sojaensis*, near the domatia. The eriophyid mites increased in number in June, followed by an increase of *A. sojaensis*. The number of *A. sojaensis* near the domatia was significantly higher when the eriophyid mites were present in the domatia than when they were absent from it. When the domatia entrance was experimentally filled with glue to prevent the eriophyid mites from being preyed upon, the density of *A. sojaensis* was significantly reduced. These results showed that the density of the eriophyid mites that inhabit the domatia affect the density of the predatory mite, *A. sojaensis*, that do not inhabit the domatia.

**Key words:** Domatia, *Cinnamomum camphora*, *Amblyseius sojaensis*, eriophyid mites

**INTRODUCTION**

Microstructures of plants variously affect small arthropods inhabiting the plants (e.g. Damman, 1987; Larsson et al., 1997). One such structure is the domatia, the small space in the vein axil on the underside of leaves of woody angiosperms, which is typically inhabited by predatory or fungivorous mites (e.g. Pemberton and Turner, 1989).

Micro-phytophagous eriophyid mites are known to inhabit the domatia of *Cinnamomum camphora* leaves (Pemberton and Turner, 1989). Preliminary observations showed the eriophyid mites (subfamily: Cecidophyinae, in identification) occurred in the domatia of *C. camphora*. These mites were seldom observed outside of the domatia. The predatory mite, *Amblyseius sojaensis* Ehara (Acari: Phytoseiidae), was observed near the domatia of *C. camphora*, but not inside it. The eriophyid mites collected from the domatia were preyed upon by *A. sojaensis* in the laboratory (Kasai, unpublished). Thus, it is plausible that the density of the eriophyid mites in the domatia may affect the density of *A. sojaensis* near the domatia. In this study, we report the seasonal occurrence of the eriophyid mites in the domatia and *A. sojaensis* near the domatia, and the effect of the density of the eriophyid mites that inhabit the domatia on the density of a predatory mite, *A. sojaensis*, that does not inhabit it.

**MATERIALS AND METHODS**

**Seasonal occurrence of the eriophyid mites in the domatia and *A. sojaensis* near the domatia.** In order to monitor the seasonal change in the abundance of the eriophyid mites in the domatia and that of *A. sojaensis* near the domatia, we sampled 1961 leaves at random from three individual *C. camphora* trees on the campus of Kyoto University once a month from April 2000 to March 2001. We counted the number of the eriophyid mites in the domatia under a stereomicroscope by dissecting the domatia, and the number of *A. sojaensis* near the domatia (radius of less than 1 cm) with the unaided eye.

**Effect of density of the eriophyid mites that inhabit domatia on the density of *A. sojaensis* that do not inhabit them.** To examine the effect of the density of the eriophyid mites on the density of *A. sojaensis*, we conducted an experiment on a *C. camphora* tree on the campus of Kyoto University

in September 2001. We randomly selected 120 shoots from the tree, and assigned them to one of the following three treatments: 1) the domatia entrance was filled with glue (woodworking bond, Konishi Corporation); 2) glue was smeared near the domatia entrance (radius of less than 1 cm) to confirm whether the predators avoided the glue; 3) no treatment (control). There were 10.04 (SE = 0.43) leaves per shoot on average. Forty replications were done for each treatment. We confirmed the presence of the eriophyid mites in the domatia prior to treatment. After 7 days, we counted the number of *A. sojaensis* near the domatia as described above.

**RESULTS**

Figure 1 shows the seasonal change in the density of the eriophyid mites and *A. sojaensis* on *C. camphora*. *A. sojaensis* was observed near the domatia, but was not observed inside the domatia. The density of eriophyid mites in the domatia showed a rapid increase from May to June, and decreased sharply thereafter. After August, the density remained low until the next spring. The density of *A. sojaensis* showed a sharp increase from May to June and then decreased abruptly by August following the same pattern as observed for the eriophyid mites. No *A. sojaensis* were observed after November. The density of *A. sojaensis* near the domatia was significantly higher when the eriophyid mites were present in the domatia than when they were absent in May and June (Table 1).

The number of *A. sojaensis* in treatment 1 (the domatia entrance was filled with glue) was significantly lower than that in each of the other two treatments (Fig. 2). The number of *A. sojaensis* did not differ between treatment 2 (glue was smeared near the domatia entrance) and treatment 3 (control). This indicates that the mites did not avoid the glue.

**DISCUSSION**

The hypotheses advanced to explain the function of the domatia assume that it may directly benefit predatory or fungivorous mites inhabiting them (e.g. O’Dowd and Willson, 1989, 1991; Walter and O’Dowd, 1992). Many studies on domatia have also been based on the hypothesis that plants obtain benefit from reduced herbivore or pathogen attack by being associated with the predatory or fungivorous arthropods (e.g. Grostal and O’Dowd, 1994; Agrawal, 1997; Agrawal et al., 2000; Norton et al., 2000). However, there has been no study on the effect of the density of the eriophyid mites that inhabit the domatia on the density of the predatory mite, *A. sojaensis* that do not inhabit the domatia.

The seasonal occurrence of *A. sojaensis* followed that of the eriophyid mites (Fig. 1). *A. sojaensis* near the domatia was much more abundant when the eriophyid mites were present in the domatia than when they were absent from it (Table 1). This suggests that the density of the eriophyid

***Significant difference between absence and presence of the eriophyid mites (p<0.001 by ANOVA).
mites in the domatia affects the density of *A. sojaensis* near the domatia. In order to demonstrate this causal relationship, we experimentally controlled the availability of the eriophyid mites for *A. sojaensis*. The lower density of *A. sojaensis* in treatment 1 (domatia entrance was filled with glue) may reflect that these predatory mites could not prey upon the eriophyid mites inhabiting domatia as food (Fig. 2). Since *A. sojaensis* cannot pass through the narrow entrance of the domatia, *A. sojaensis* may prey upon only the eriophyid mites that disperse from the domatia. The timing and amount of the eriophyid mites dispersing from the domatia should be clarified in the future.

The present study demonstrated that the density of the eriophyid mites that inhabit the domatia of *C. camphora* affects the density of the predatory mite, *A. sojaensis* that does not inhabit the domatia. However, further information on the life history of *A. sojaensis* remains to be examined in the future, such as whether or not *A. sojaensis* preys solely upon the eriophyid mites, and how *A. sojaensis* come through the season when the eriophyid mites are absent.

**ACKNOWLEDGEMENTS**

I thank Dr. F. Kadono of Chiba Prefectural Agriculture Research Center for the identification of the eriophyid mites. I also thank Dr. T. Nishida and Dr. S. Oku of Kyoto University for valuable suggestions on this study, and Dr. H. Amano of Chiba University for the identification of the phytoseiid mites.
