Materials which can be combined with riboflavin specifically based on smart functionalized polymer were studied for their ability to selectively extract riboflavin from beer. The extraction was done directly by the affinity interaction of riboflavin with the riboflavin aptamer or riboflavin binding protein (RBP). Poly(N-isopropylacrylamide) (PNIPAAm) was introduced as a carrier and modified with riboflavin aptamer and RBP, respectively, in order to be conducive to the separation of riboflavin originally present in the beer. The produced complexes can be readily separated from the aqueous phase and benefited from the temperature sensitive property of this smart polymer. The study showed riboflavin could be selectively removed from a standard solution and beer satisfactorily and the nonspecific binding was almost negligible. In the manufacturing process of beer, this separation method has a great potential to prolong the storage period of beer and improve the quality of the products.

Introduction

Riboflavin is an essential vitamin in human nutrition occurring in a wide variety of food products, and it is produced biotechnologically and used in vitamin enriched food and food supplements.3-4 Additionally, riboflavin is an important biological redox cofactor that can act as the universal precursor of the flavin adenine dinucleotide and coenzyme flavin mononucleotide.5 In view of this, riboflavin is indispensable for the activity of a wide variety of metabolic enzymes in microbes, plants and animals, and it is very important for human and animal health.6

However, in the beer manufacturing industry, the effect of riboflavin is not as positive as it is in the human body. Beer is a fermented alcoholic beverage brewed from malt and flavored with hops.7,3 Owing to its contribution to bitterness, the hop plant is regarded as an essential raw material in the brewing process that can lead to a balanced and pleasant taste of beer products.9 As a result, the hop plant has been widely accepted among all the herbs that have been used in beer.10 Substances in hops can produce iso-α-acids, which are intensely bitter.11 When exposed to visible light, especially in the 350 – 500 nm range, with the intervention of a photosensitizer such as riboflavin, the quality of beer will be affected.12,13 Because light of this wavelength can trigger the photodegradation of iso-α-acids, this results in the formation of the volatile compound 3-methyl-2-buten-1-thiol (MBT), which has a foul smell. This phenomenon is generally referred to as “lightsstruck flavor” (LSF).14 Experiments have proved that the concentration of MBT increases linearly with an increase in riboflavin concentration.15 Accordingly, the concentration of riboflavin in beer is a major factor for assessing flavor stability.16,17 Riboflavin removal has been proposed as a strategy for controlling sunstruck flavor formation.18 Manesisiotis et al. reported a kind of water-compatible imprinted polymers for selective depletion of riboflavin from beverages. The hydrophilic polymers, when subjected to beer, showed a maximum removal of 86%.19

In this study, the riboflavin aptamer and riboflavin binding protein (RBP) were introduced respectively as a carrier and modified with riboflavin aptamer and RBP, respectively, in order to be conducive to the separation of riboflavin originally present in the beer. The produced complexes can be readily separated from the aqueous phase and benefited from the temperature sensitive property of this smart polymer. (Received January 22, 2018; Accepted March 1, 2018; Published July 10, 2018)
Riboflavin binding proteins could form the combination to selectively extract the riboflavin. This might be conducive to limiting sunstruck flavor formation in beer.

In order to separate the riboflavin from beer, and thus prolonging the storage time of products, thermosensitive polymer poly(N-isopropylacrylamide) (PNIPAAm) was utilized as a coupling object with the riboflavin aptamers (PNIPAAm-co-RAP) and RBP (PNIPAAm-co-RBP), respectively.30–32 Thermosensitive polymers are soluble in a certain solvent as homogenous solutions at low temperatures but a phase separation is induced by surpassing a certain temperature threshold, which is defined as the lower critical solution temperature (LCST).33 In view of the above principle, separation of riboflavin can achieve good effects by changing the temperature in a homogenous solution. By integrating the advantages of the high affinity of the riboflavin aptamer and RBP with riboflavin, the two kinds of smart functionalized polymers may open a new path to extending the shelf life of beer.

**Experimental**

**Materials and reagents**

N-Isopropylacrylamide (NIP), acrylic acid N-hydroxysuccinimide ester (NAS), ammonium persulfate (APS), N,N,N,N-tetramethylethlenediamine (TEMED), tris(hydroxymethyl)aminomethane hydrochloride (Tris), sodium phosphate dibasic, sodium phosphate monobasic dihydrate, sodium chloride, ethylenediaminetetraacetic acid disodium salt (EDTA) and RBP were obtained from Sigma-Aldrich (USA). All the above reagents were of analytical-reagent grade or higher. Hydrochloric acid was purchased from Sinopharm Chemical Reagent Co., Ltd. Ultrapure water was obtained by a Milli-Q academic purification set (Millipore, USA). Fluorometric spectra were obtained with an RF-5301PC spectrophotometer (Shimadzu, Japan) equipped with a 150-W xenon lamp (Ushio Inc, Japan). ZF-20D ultraviolet analyzer produced by Gucun Photoelectric Instrument Factory (Shanghai, China) was used in this study.

**Determination of the concentration of riboflavin in beer**

First, 3.8 mg riboflavin was dissolved in 100 mL Tris–HCl buffer solution (Tris 10 mM, NaCl 150 mM, EDTA 1 mM) as a standard solution and stored at 4°C away from light before use. In order to determine the amount of riboflavin in beer, the fluorescence intensities of different concentrations (0.10, 0.50, 1.0, 2.0, 3.0, 4.0 μM) of riboflavin were detected to draw a standard curve. Afterwards, the fluorescence intensity of the same volume of Harbin beer sample was recorded to calculate the concentration of riboflavin in the sample. Subsequently, standard addition experiments of different concentrations (0, 3.0, 6.0, 9.0, 12 μM) of riboflavin was conducted to further prove the amount of riboflavin in the beer sample.

**Investigation of the binding effect between aptamers and riboflavin**

Firstly, different concentrations of aptamer A were mixed with the same concentration of aptamer B, respectively, for 30 min to form DNA duplexes. Next, 1.0 μM riboflavin was added into the reaction products for 1 h. Later, the fluorescence intensities of riboflavin before and after being trapped were recorded.

**Preparation and investigation of PNIPAAm-co-RAP**

As shown in Fig. 1A, PNIPAAm-co-RAP was prepared by utilizing NAS as a coupling reagent. Active ester groups can react with amino groups modified on DNA and the C=C of NAS can polymerize with the C=C of NIP. Briefly, 230 μL of 100 μM aptamer A was coupled with 200 μL NAS in DMSO of 2.0 mg mL⁻¹, and incubated at 37°C under stirring for 1 h. Afterwards,

Ultrapure water was obtained by a Milli-Q academic purification set (Millipore, USA). Fluorometric spectra were obtained with an RF-5301PC spectrophotometer (Shimadzu, Japan) equipped with a 150-W xenon lamp (Ushio Inc, Japan). ZF-20D ultraviolet analyzer produced by Gucun Photoelectric Instrument Factory (Shanghai, China) was used in this study.
60 mg NIP, 10 mg APS and 10 μL TEMED were added into the coupling product in 5 mL of PBS buffer solution (NaH₂PO₄ 10 mM, Na₂HPO₄ 10 mM, NaCl 15 mM, pH 7.4). After polymerization for 2 h by continuous shaking at 25°C, PNIPAam-co-RAP was precipitated at 37°C for 5 min and separated from unreacted monomers, aptamer A and small molecule impurities by centrifugation for 5 min at 37°C (8000 rpm) and then resolved in 5 mL of cold PBS buffer solution. The purification cycle was replicated three times. The last time, PNIPAam-co-RAP was resuspended in 500 μL of PBS buffer solution and stored at 4°C before use.

FAM-DNA, which could react with aptamer A according to the strict complementary nature of the base pairs, was utilized to determine the concentration of aptamer A in PNIPAam-co-RAP of the final product. Firstly, different concentrations (0.010, 0.10, 0.50, 1.0, 2.0, 4.0 μM) of FAM-DNA were added into 30 μL PNIPAam-co-RAP solutions. The reaction volume was 300 μL. Next, the mixtures were shaken at 25°C for 30 min to form DNA double stranded structures. The fluorescence signal of each product was individually analyzed and the intensity was recorded. Simultaneously, the fluorescence intensities of different concentrations (0.10, 0.50, 0.80, 1.0, 1.5 μM) of FAM-DNA were detected to draw a standard curve. Afterwards, the concentration of aptamer A in PNIPAam-co-RAP was calculated according to the maximum fluorescence intensity and the standard curve.

Preparation and investigation of PNIPAam-co-RBP

As shown in Fig. 1B, PNIPAam-co-RBP was also prepared by utilizing NAS as a coupling reagent. Active ester groups can react with amino groups of RBP and the C=C of NAS can be utilized as that of aptamer A in PNIPAam-co-RAP. First, different concentrations (0.010, 0.10, 0.50, 1.0, 2.0, 4.0 μM) of FAM-DNA were added into 30 μL PNIPAam-co-RAP solutions. The reaction volume was 300 μL. Next, the mixtures were shaken at 25°C for 30 min to form DNA double stranded structures. The fluorescence signal of each product was individually analyzed and the intensity was recorded. Simultaneously, the fluorescence intensities of different concentrations (0.10, 0.50, 0.80, 1.0, 1.5 μM) of FAM-DNA were detected to draw a standard curve. Afterwards, the concentration of aptamer A in PNIPAam-co-RAP was calculated according to the maximum fluorescence intensity and the standard curve.

Procedure of PNIPAam-co-RBP applied in the extraction of riboflavin

Similarly, different volumes of PNIPAam-co-RBP were precipitated at 37°C for 5 min and centrifuged for 3 min at 37°C (13000 rpm) and then resolved in 99 μL of cold PBS buffer. Next, as shown in Fig. 2B, 1.0 μM standard solution was added into each solution above and reacted at 25°C for 4 h. The processing method of the products was similar to that of PNIPAam-co-RAP. The concentrations of riboflavin were determined by measuring the fluorescence intensities of the supernatants.

The material modified with streptavidin (SA) (Supporting Information 2) (PNIPAam-co-SA) was synthesized and reacted with a standard solution with the same concentration as PNIPAam-co-RBP to verify that the effects of nonspecific adsorption are negligible.

Extraction of riboflavin in beer

Firstly, PNIPAam-co-RBP condensed to different concentrations benefited from the temperature sensitive property of the material. Different volumes of PNIPAam-co-RBP solutions were precipitated at 37°C for 5 min and centrifuged for 3 min at 37°C (13000 rpm) and then resolved in 98 μL of cold PBS buffer. Next, as shown in Fig. 2A, the same concentration of aptamer A as that of aptamer A in PNIPAam-co-RAP and 1.0 μM standard solution were added respectively and reacted at 25°C for 4 h to form DNA duplex aptamers and trapped the target. Later, products were precipitated at 37°C for 5 min and centrifuged for 3 min at 37°C (13000 rpm). The supernatants were collected and the fluorescence intensities were recorded to determine the concentrations of riboflavin remaining in the samples.

In order to verify that the extraction of the target was based on the specific binding between captures and target rather than nonspecific adsorption, the same concentration of material coupled with DNA 1 (Supporting Information 1) was utilized in the experiments. The DNA duplex in this experiment was formed by DNA 1 and DNA 2. The procedure for riboflavin extraction was similar to that for PNIPAam-co-RAP.
Results and Discussion

The concentration of riboflavin in beer

As shown in Fig. 3A, the fluorescence intensity increased gradually with the increase of the concentration of riboflavin, and the regression equation was \( y = 197.7x - 0.65 \) (\( R^2 = 0.99 \)). The fluorescence intensity of riboflavin in Harbin beer was described in Fig. 3B. According to the standard curve of riboflavin in Fig. 3A, the concentration of riboflavin in Harbin beer was calculated and the result was 1.0 \( \mu \)M. The regression equation of standard addition experiment in Fig. 3C was \( y = 64.41x + 160.3 \) (\( R^2 = 0.99 \)), which further proved the reliability of the results. Figure 3D shows the difference between different samples (buffer, riboflavin solution and Harbin beer) excited by ultraviolet lamp, in which the difference between the different samples was obvious. The difference of the picture of fluorescence between Harbin beer and riboflavin solution was likely due to the influence of other substances in beer.

The binding effect between aptamers and riboflavin

Riboflavin DNA duplex aptamers utilized in this study contained AP sites. Riboflavin can bind selectively to the receptor nucleotide opposite an AP site in a DNA duplex through stacking interactions and hydrogen bonding. When the AP site was flanked by guanine bases, the fluorescence of riboflavin bound to the AP site was strongly quenched. This feature of the riboflavin-duplex interaction was of great practical value. In this study, riboflavin can be trapped and quenched by the riboflavin aptamer. Therefore, the alteration of fluorescence intensity of riboflavin can be utilized to analyze the binding effect between aptamers and riboflavin.

As shown in Fig. 4, in the presence of DNA duplex aptamers, as mentioned earlier, riboflavin was trapped by aptamers and its fluorescence was quenched. With the increase of the concentration of DNA duplex aptamers, the effect was more obvious. The fluorescence intensity of riboflavin only remained 22.44% when the concentration of aptamers reached 20 \( \mu \)M. This proved the existence of interaction between riboflavin aptamer and riboflavin and this can be further applied.

Preparation and investigation of PNIPAAm-co-RAP

The fluorescence intensities of the complexes in the presence of various FAM-DNA concentrations are shown in Fig. 5A. Initially, the fluorescence intensity increased with increasing...
concentration of FAM-DNA. Nevertheless, when the concentration of FAM-DNA increased to a certain degree, 2.0 μM, which was close to the maximum amount with which aptamer A can combine, the fluorescence intensity reached a plateau. According to the regression equation (\( y = 663.45x - 8.82 \) (\( R^2 = 0.99 \))) in Fig. 5B derived from the standard curve of FAM-DNA, the concentration of aptamer A coupled with PNIPAAm was 0.70 μM. The concentration of PNIPAAm-co-RAP in the experiment was diluted 10 times, so the original concentration of PNIPAAm-co-RAP was recognized as 7.0 μM. And it was used to define the concentration of the material.

Preparation and investigation of PNIPAAm-co-RBP

The amount of RBP coupled with PNIPAAm in the final product can be determined by the intrinsic fluorescence of RBP. The fluorescence intensities of various RBP concentrations are shown in Fig. 5C and the regression equation is \( y = 47.85x + 14.7 \) (\( R^2 = 0.99 \)). The fluorescence intensity of PNIPAAm-co-RBP is described in Fig. 5C. According to the regression equation above, the concentration of RBP coupled with PNIPAAm is calculated and the result is 3.0 μM. And it was used to define the concentration of the material.

Smart functionalized polymers applied in extraction of riboflavin

Different concentrations of DNA duplex aptamers in PNIPAAm-co-RAP were incubated in 1.0 μM standard solution and the results are shown in Fig. 6A. With the increase of the concentration of DNA duplex aptamers, the amount of riboflavin that remained in solution decreases gradually. In other words, the amount of riboflavin captured and extracted increases. The amount of riboflavin in the solution no longer decreased when the concentration of DNA duplex aptamers reached 21 μM. The capture capacity of this material was saturated with a 97% maximum riboflavin depletion. By contrast, as shown in Fig. 6(b), DNA duplex formed by DNA 1 and DNA 2 can extract only 13% riboflavin in the solution, which was much lower than that with DNA duplex aptamers. This showed that nonspecific adsorption in this experiment is weak.

Similarly, for PNIPAAm-co-RBP, different concentrations of this material were also incubated in 1.0 μM standard solution. As shown in Fig. 6B, with the increase of the concentration of PNIPAAm-co-RBP, the amount of riboflavin that remained in solution decreased gradually, as more riboflavin was captured and extracted by this biomaterial. The extraction ability of PNIPAAm-co-RBP towards riboflavin reached an extreme value when the concentration of RBP reached 3.0 μM. Compared with PNIPAAm-co-RAP, PNIPAAm-co-RBP had a similar effect on riboflavin extraction with a nearly 97% maximum depletion. The nonspecific adsorption of proteins on the target was further investigated. As shown in Fig. 6D(b), PNIPAAm-co-SA had almost no capture capability for riboflavin and can be ignored. This proved that the extraction of this material is specific to the target.

The results of smart functionalized polymers PNIPAAm-co-RAP and PNIPAAm-co-RBP for selective extraction of riboflavin from beer are shown in Figs. 6C(c) and Fig. 6D(c), respectively. Compared with the fluorescence intensity of the original riboflavin in Harbin beer, PNIPAAm-co-RAP extracted nearly 78% of the target from the samples and PNIPAAm-co-RBP obtained a 90% riboflavin depletion. It can be noted that PNIPAAm-co-RBP had better ability to extract riboflavin than PNIPAAm-co-RAP.

In order to verify that this smart functionalized polymer, PNIPAAm-co-RBP, has good riboflavin extraction effectiveness for different beers, sample 2, sample 3 and sample 4 were introduced into the experiments and incubated with 3.0 μM PNIPAAm-co-RBP. As shown in Fig. 7, this material has good effect on the extraction of riboflavin from different beer samples.

Conclusions

The existence of riboflavin could affect the shelf life of beer. In order to extract the riboflavin in beer and promote the development of storing technology in the beer industry, smart functionalized polymers PNIPAAm-co-RAP and PNIPAAm-co-RBP were prepared with a simple method. Riboflavin aptamers and RBP can bind tightly to riboflavin, which ensured that the target in beer can be captured. In addition, these smart functionalized polymers displayed a controllable conformation change below or above its LCST, which was conducive to the separation of riboflavin in samples. Utilizing these advantages, the riboflavin in beer can be extracted with high depletion and the nonspecific binding was almost negligible. This kind of new material offers good prospects for prolonging the shelf life of beer and enhancing the quality of beer.
