The solvent extraction of molybdenum(VI) and uranium(VI) with α-hydroxy oxime, 5,8-diethyl-7-hydroxydodecan-6-one oxime (LIX 63) and their stripping behavior have been investigated. A cationic species of Mo(VI) was preferentially extracted in an acidic region, and the extraction was greatly depressed above pH 4. Uranium(VI) species were extracted in a nearly neutral region and selectively stripped with a dilute acid. The transport of these metal complexes across a supported liquid membrane (SLM) has been investigated employing LIX 63 as a mobile carrier. Uranium(VI) was selectively transported on the product side, while Mo(VI) species was retained in the SLM in the low pH region and remained in the feed solution in the nearly neutral region. This improves their mutual separation, and only U(VI) was recovered in the product solution, depressing the transport of Mo(VI).

Keywords Molybdenum, uranium, solvent extraction, liquid membrane transport, LIX 63, separation

Uranium(VI) is usually accompanied by molybdenum(VI) and other metals in natural resources.1 Separation of U(VI) from Mo(VI) is of importance for attainment of the final products of high purity. The solvent extraction of Mo(VI) and U(VI) from acidic solutions has been investigated using a variety of extractants such as tertiary amines, alkylphosphates and sulfoxides.2,3

A chelating extractant, α-hydroxyl oxime (LIX 63), is useful in the extraction of cationic species, and it has been employed for the extraction of Mo(VI) from acidic solutions.4,5 In our previous works, Mo(VI) was effectively extracted with LIX 63 from an acidic region, in which Mo(VI) forms an extractable cationic species of MoO$_2^{2+}$,6,7 while uranium(VI) was extracted in a weakly acidic region.8

Owing to superior extraction and stripping characteristics, LIX 63 is also available for a mobile carrier to transport metal species through liquid membranes. The transport of U(VI) has been achieved across a supported liquid membrane impregnated with LIX 63, and U(VI) was effectively concentrated by uphill transport.9 The successive transport of Mo(VI) was accomplished through the double liquid membranes containing different kinds of carriers, LIX 63 for cationic species and trioctylmethyl ammonium chloride (TOMAC) for anionic species.7

In this work, the extraction of Mo(VI) and U(VI) with LIX 63 and their stripping behavior have been investigated. A supported liquid membrane employing LIX 63 as a mobile carrier has been demonstrated for the separation of U(VI) from Mo(VI) by the selective transport of U(VI).
Experimental

Liquid-liquid extraction
5,8-Diethyl-7-hydroxydodecan-6-one oxime (LIX 63; Henkel) was diluted with kerosene (Wako Pure Chemical Ind.). An aqueous solution containing 10 ppm of each Mo(VI) and U(VI) was shaken with an equal volume of LIX 63 solution at 25°C. The aqueous pH was controlled with H₂SO₄, 0.01 M (= mol dm⁻³) (H,Na)CH₃COO or 0.01 M NH₄(OH,Cl). The concentrations of metals in the aqueous phase were determined by ICP-AES with a SEIKO SPS 1200 A spectrometer.

Liquid membrane transport
A PTFE membrane (POREFLON FP-045; Sumitomo Electric Ind.) was used as an inert support, which has a thickness of 80 µm, a porosity of 74%, an average pore size of 0.45 µm and an area of 26 cm². The liquid membrane impregnated with LIX 63 in kerosene was contacted with a feed solution (100 cm³) containing 10 ppm of each Mo(VI) and U(VI) and an equal volume of a stripping product solution. Transport experiments were carried out in a similar manner described in the previous paper. Concentrations of metals in the feed and product solutions were measured by ICP-AES at selected intervals.

Results and Discussion

Liquid-liquid extraction of Mo(VI) and U(VI)
Extraction of Mo(VI) and U(VI) with LIX 63 from a dilute sulfuric acid solution was examined by varying contact time. As Fig. 1 shows, the extraction of Mo(VI) was fairly fast and Mo(VI) was completely removed from the aqueous phase after 1 min. The extraction of U(VI) more slowly increased. Their mutual separation is likely performed by preferential extraction of Mo(VI) in a short contact time.

As Fig. 2 shows, the extraction of Mo(VI) increased with LIX 63 concentration up to 0.05 M and became quantitative at higher concentrations, while no extraction of U(VI) occurred below 0.1 M LIX 63.

Several forms of Mo(VI) are present in aqueous solutions and MoO₂³⁻ is a predominant species below pH 2, while U(VI) exists in cationic species in a wide pH region.

Fig. 1 Extraction with 0.1 M LIX 63 in kerosene from 0.01 M H₂SO₄.

Fig. 2 Effect of LIX 63 concentration on the extraction from 0.01 M H₂SO₄. 1 min.

Fig. 3 Effect of pH on the extraction with 0.01 M LIX 63. 10 min.
The extraction of these cationic species proceeds as follows:\textsuperscript{6,8}
\begin{equation}
\text{MO}_2^{2+} + 2\text{HL}(\text{o}) \rightarrow \text{MO}_2\text{L}_2(\text{o}) + 2\text{H}^+ \quad (1)
\end{equation}
where \( \text{M} \) represents \( \text{Mo(VI)} \) or \( \text{U(VI)} \), \( \text{HL} \) represents LIX 63 and the subscript (o) refers to the organic phase.

Chemical species of these metal ions were complicated depending on an aqueous acidity, and extraction behavior was investigated by varying the pH. The extraction of Mo(VI) was effective in an acidic region and sharply fell down above pH 5 due to the formation of an unextractable anionic \( \text{MoO}_4^{2-} \) species, as shown in Fig. 3. The extraction of U(VI) increased with increasing pH above 2 and attained a maximum around pH 6. In higher pH regions, the U(VI) extraction gradually decreased due to the presence of the hydrolyzed forms. Though the extraction separation of Mo(VI) from U(VI) was successful in the low pH region, the selective extraction of U(VI) above pH 6 is also promising.

**Selective stripping**

Appropriate aqueous conditions are of importance for selective stripping of the desired metal ion. After Mo(VI) and U(VI) had been firstly extracted from pH 5.5 for 10 min, stripping was tested by using prospective agents. As Fig. 4(a) shows, U(VI) was selectively stripped into 0.1 M H\(_2\)SO\(_4\) after 3 min, while Mo(VI) remained in the organic phase. As Fig. 4(b) shows, Mo (VI) was nearly completely stripped with 0.05 M NaOH after 1 h, but 40\% of U(VI) was stripped together.

![Fig. 4 Stripping with (a) 0.1 M H\(_2\)SO\(_4\) and (b) 0.05 M NaOH. Extraction: 0.01 M LIX 63, pH 5.5, 10 min.](image)

Transport separation through LIX 63-SLM

Based on the extraction and stripping behavior of individual metal species, SLM transport experiments were performed using LIX 63 as a mobile carrier. The transport of Mo(VI) and U(VI) was investigated by varying the pH of the feed solution. For selective stripping of U(VI), 0.1 M H_2SO_4 was used as a product solution.

Figure 5 shows typical transport profiles of each metal ion against shaking time. At a low pH of 2.2 (Fig. 5 (a)), Mo(VI) was removed from the feed solution and retained as the complex with LIX 63 in the SLM phase, while U(VI) was poorly extracted and remained in the feed side. As the feed pH increased to 4.6 (Fig. 5(b)), the both metal ions were removed from the feed solution, and only U(VI) was selectively transported to the product side. The Mo(VI) species retained in SLM can be removed by washing with an alkaline solution such as 0.1 M NaOH after the transport experiments. At a neutral pH 6.9 (Fig. 5(c)), U(VI) was transported into the product side, while Mo(VI) remained in the feed side. The transport of metal species thus proceeded in accordance with the solvent extraction behavior mentioned above.

Figure 6 shows the effect of the pH of the feed solution on the recovery in the product solution. The recovery of U(VI) increased with increasing pH up to about 6 and then gradually decreased at higher pH values owing to the suppression of extraction from the feed solution. No portion of Mo(VI) passed through the membrane to the product side and the separation of U(VI) from Mo(VI) was successfully achieved.
