(Received for publication January 9, 1998)

The structure of a novel antitumor antibiotics FD-594 (1), produced by Streptomyces sp. TA-0256, was determined to have a glycosylated pyrano[4',3':6,7]naphtho[1,2-b]xanthene skeleton by means of spectral data. The biosynthetic studies of the chromophore of 1 was also carried out by feeding experiments with [1-13C]-, [2-13C]-, and [1,2-13C2] sodium acetate. The labeling pattern was determined by 13C NMR including 2D INADEQUATE experiments, which allowed us to elucidate that the chromophore of 1 is derived from 14 acetate, followed by the loss of one carbon atom.

In the course of screening for new antitumor antibiotics, it was found that an acetone extract from Streptomyces sp. TA-0256 inhibited growth of several cancer cell lines, and subsequent bioassay-guided purification of the active principle resulted in the isolation of a new antibiotics, designated as FD-594 (1). In this paper, we wish to report the structure elucidation of 1 by making extensive use of the 13C-enriched metabolite. Also described is the biosynthetic pathway of the chromophoric part of 1.

Results and Discussion

The physico-chemical properties of 1 are summarized in Table 1. The molecular formula of 1 was established as C47H56O20 by the HR-FAB mass spectrometry. The IR absorptions at 1667 and 1624 cm⁻¹ suggested the existence of ¼, ¼-unsaturated carbonyl groups. The UV-visible maxima at 420 and 363 nm in methanol were shifted to 440 and 379 nm, respectively, in the presence of NaOH in methanol, which strongly suggested the presence of phenolic hydroxyl group(s). The 1H NMR spectra showed the presence of three phenolic protons (δH 11.8, 11.9, and 12.3) in CDCl3. The 1H NMR data

Fig. 1. Structures of FD-594 (1).
of I are shown in Table 2.

The $^{13}$C NMR spectra of I displayed limited carbon signals (44–45 signals) in various solvents (CDCl$_3$, acetone-$d_6$, DMSO-$d_6$, pyridine-$d_5$) probably due to slow conformational exchange. Since the characteristically high degree of unsaturation suggested the origin of the chromophore of I to be polyketide (polyacetate, rather), we undertook preparation of $^{13}$C-enriched specimen for $^{13}$C NMR analysis by feeding either [1-$^{13}$C]-or [2-$^{13}$C] sodium acetate into the growing culture of Streptomyces TA-0256. The resulting $^{13}$C-labeled antibiotic was extracted from the mycelia and purified by a flash chromatography and a preparative reverse phase HPLC. The $^{13}$C NMR spectra of I labeled from [1-$^{13}$C]- and [2-$^{13}$C] sodium acetate showed 13 and 14 enriched signals, respectively. These $^{13}$C-enriched products were extremely useful for the following structure determination. The $^{13}$C NMR peak intensities of I labeled by [1-$^{13}$C]- and [2-$^{13}$C] sodium acetate feeding were summarized in Table 3. By combining all the $^{13}$C NMR data obtained from labeled and non-labeled I together, we were able to locate the presence of 47 carbons, which were then classified into several categories, i.e. two $\alpha,\beta$-unsaturated carbonyl carbons (δC 186.2 and 170.3), ten $sp^2$ quaternary carbons (δC 159.0, 153.8, 152.1, 151.3, 148.9, 144.7, 140.1, 140.0, 138.9, and 136.9), three $sp^2$ methine carbons (δC 129.6, 113.3, and 106.3), five $sp^2$ quaternary carbons (δC 115.4, 112.0, 111.0, 110.0, and 106.3), and five $sp^3$ methine carbons (δC 138.9, 136.9, 136.9, 136.9, and 136.9).

\(^a\) Peak intensities were normalized to the carbon signal of 8-OCH\(_3\).

The 1H-1H COSY and HMBC spectra of 1, as well as 13C-enriched 1, confirmed the homo- and heteronuclear connectivities in 1, which are shown in Figure 2. The HMBC correlations of the C-12 with the anomeric proton of H-1' indicated the glycosylated position. Other HMBC correlations from the aromatic protons, H-3, H-6, H-7, and the phenolic protons suggested the structure of the aglycon part of 1 as 3-propylpyrano[4',3':6,7]naphth[1,2-b]xanthene skeleton.

The carbon connectivities of the aglycon part of 1 was clearly indicated by the HMBC of the pyranose units, which was further verified by acetylation of 1 to its octa-aceacetate 2 [FAB-MS m/z: 1299 (M\(^+\) + Na)]. Significant shifts of the methine signals to the lower field were observed at H-3' (\(\delta_H 5.2\)), H-3" (\(\delta_H 5.2\)), and H-4''' (\(\delta_H 4.88\)) by acetylation.
Fig. 2. $^1$H-$^1$H COSY and HMBC connectivities of 1.

Further confirmed by the use of labeling with [1,2-$^{13}$C$_2$]sodium acetate by similar feeding experiment as described above. The $^{13}$C NMR spectrum of 1 enriched with the double-labeled acetate showed all carbons of the aglycon part of 1 as triplet except for the methoxy carbon and C-8a. The latter (C-8a) was observed as an enriched singlet. All the C-C spin couplings due to incorporation of intact acetate were confirmed by 2D INADEQUATE experiment as shown in Figure 3, which clearly indicated the connectivities of acetate units in the aglycon part of 1 as summarized in Figure 4. The coupling constants obtained for the [1,2-$^{13}$C$_2$]acetate enriched 1 are also listed in Table 3. Thus, the structure of 1 was

Fig. 3. The 2D INADEQUATE spectrum of 1 enriched with the double labeled acetate.

Fig. 4. The carbon-carbon connectivities in the aglycon part of 1 deduced by double-labeled acetate.

Further confirmed by the use of labeling with [1,2-$^{13}$C$_2$]sodium acetate by similar feeding experiment as described above. The $^{13}$C NMR spectrum of 1 enriched with the double-labeled acetate showed all carbons of the aglycon part of 1 as triplet except for the methoxy carbon and C-8a. The latter (C-8a) was observed as an enriched singlet. All the C-C spin couplings due to incorporation of intact acetate were confirmed by 2D INADEQUATE experiment as shown in Figure 3, which clearly indicated the connectivities of acetate units in the aglycon part of 1 as summarized in Figure 4. The coupling constants obtained for the [1,2-$^{13}$C$_2$]acetate enriched 1 are also listed in Table 3. Thus, the structure of 1 was
Fig. 5. Structures of BE-13973X and MS 901809.

Fig. 6. Degradation of 1.
deduced to be 12-[(O-2, 6-dideoxy-3-O-methyl-β-arabino-hexopyranosyl-(1→4)-O-2, 6-dideoxy-β-arabino-hexopyranosyl-(1→4)-2, 6-dideoxy-β-arabino-hexopyranosyl)-oxy]-3,4,6,7-tetrahydro-6, 7, 13, 15, 16-pentahydroxy-8-methoxy-3-propylpyrano [4',3':6,7]-naphtho [1, 2-b] xanthene-1,14-dione. The structure of 1 was actually closely related to BE-13973X2) and MS 9018093), both of which were reported to be isolated also from Streptomyces.

The absolute configurations of the oleandroside and the olivoside were determined as shown in Figure 6. Acidic methanolysis of 1 gave the aglycon 3, methyl olivoside 4, and methyl oleandroside 5. The aglycon 3 was in good accordance with BE-13793XA derived from BE-13793X in all spectroscopic respects. Further acid hydrolysis of these glycosides 4 and 5 afforded the known sugar 6 and 7. The absolute stereochemistry of the obtained 6 and 7 was determined to be D by their optical rotations [6: +18.9° (lit. +20°)4], 7: -12.0° (lit. -12.5°)5]. The absolute stereochemistry of the aglycon moiety of 1 is now under study.

The carbon skeleton of the chromophore of 1 appeared to be constructed through a polylactate equivalent as deduced by feeding experiments of labeled acetate. As a results, the biosynthetic pattern of the chromophore of 1 is postulated to be as shown in Figure 7. In an early stage, the benzo[2]naphthacene quinone chromophore may first be derived from 14 acetate units as in the case of pradimicin family of antibiotics6~8). Thereafter, the Baeyer-Villiger type oxidation occurs at a quinone carbonyl group, followed by additional oxidation and decarboxylation to yield a ring-opened intermediate. Recyclization via path a leads to 1, an alternative recyclization via path b may afford structurally related MS 901809.

In summary, the structure of a novel antitumor antibiotics FD-594 (1) was determined to have a glycosylated pyrano [4',3':6,7]naphtho [1, 2-b]xanthene skeleton by means of spectral data including various 13C-enriched products, prepared by feeding experiments with [1-13C]-, [2-13C]-, and [1,2-13C2]sodium acetate. The labeling pattern was unambiguously determined by the 2D INADEQUATE experiment. The labeling experiments additionally allowed us to postulate the biosynthesis of the chromophore of 1, which appears to be derived from 14 acetate units accompanied by the loss of one carbon atom.

Experimental

General

UV-visible spectra were recorded on a Shimadzu UV-160A spectrophotometer. IR spectra were taken on a HORIBA FT-710 spectrometer and optical rotations were measured on a JASCO DIP-360 polarimeter. FAB-MS and HRFAB-MS were recorded by a JEOL
spectrometer model JMS-AX 505HA. The 1D and 2D NMR spectra were obtained on JEOL LA-300 and/or 400 spectrometers. A flash column chromatography was performed using Merck Silica gel 60 (230–400 mesh). Preparative HPLC were carried out using a Hitachi L-6250 HPLC system with a Senuh Pak Pegasil ODS column (20 i.d. x 250 mm). Sodium [1-13C], [2-13C], and [1,2-13C2]acetates were purchased from ISOTEC Inc.

Acetylation of I
FD-594 (I) (10.2 mg) was acetylated overnight with Ac2O (0.4 ml) in pyridine (0.8 ml) at room temperature. After concentration of the mixture, the crude product was purified by a flash silica gel column chromatography with hexane-EtOAc (2:3) and preparative HPLC (85% MeOH aq.) to give 4.0 mg of octa-acetylated FD-594 (2), pale yellow powder, mp 152–155°C; [α]D: +179° (c 0.89, CHCl3); UV λmax/nm in methanol (ε): 364 (4100), 324 (6900), 273 (38300), 218 (30300); IR νmax/cm⁻¹ (CHCl3): 1741, 1664, 1617, 1604, 1479, 1463, 1371, 1236, 1199, 1060; FAB-MS m/z: 1299 (M+Na); 1H NMR (benzene-d6) δ: 7.35 (1H, d, J=9.3 Hz), 7.32 (1H, s), 6.85 (1H, d, J=9.3 Hz), 6.28 (1H, d, J=3.4 Hz), 5.2 (2H, m), 4.88 (1H, t, J=9.3 Hz), 4.75 (1H, dd, J=2.0, 9.3 Hz), 4.37 (1H, dd, J=2.2, 9.5 Hz), 3.95 (1H, br), 3.29 (t, J=9.0 Hz), 3.28 (t, J=9.0 Hz), 3.15 (1H, t, J=9.3 Hz), 1.99 (1H, ddd, J=2.2, 5.4, 12.3 Hz), 1.91 (3H, s), 1.90 (1H, m), 1.86 (3H, s), 1.77 (3H, s), 1.71 (dt, J=9.8, 12.3 Hz), 1.65 (dt, J=9.5, 12.4 Hz), 1.60 (3H, s), 1.60 (1H, m), 1.49 (6H, s), 1.27 (1H, d, J=5.8 Hz), 1.22 (1H, d, J=6.1 Hz), 1.21 (1H, d, J=5.8 Hz), 1.20 (2H, m), 0.71 (3H, t, J=7.1 Hz); 13C NMR (benzene-d6) δ: 174.7, 169.8, 169.6, 169.4 (2C), 169.3, 169.2 (2C), 168.2, 161.6, 151.5, 150.6, 149.7, 146.5, 145.7, 143.3, 141.4, 140.9, 139.7, 132.0, 128.6, 126.0, 125.7, 121.9, 121.3, 118.1, 117.3, 115.2, 100.4, 100.1, 99.5, 81.7, 81.6, 78.2, 77.5, 76.0, 72.0, 71.8, 70.9 (2C), 70.8, 69.6, 64.6, 62.5, 56.1, 37.6, 36.9 (3C), 33.6, 21.3 (2C), 21.1, 21.0, 20.7, 20.6, 20.4, 20.2, 18.5, 18.4 (2C), 18.1, 13.8.

Methanolysis of I
A mixture of I (79 mg) and approximately 1.0 ml of Dowex 50W-X8 (H⁺ form) ion-exchange resin in 4.0 ml of methanol was stirred at room temperature for 6 hours. The resin was filtered off and the filtrate was concentrated. Silica gel chromatography (EtOAc·CHCl₃ = 1:1 to CHCl₃·MeOH·H₂O = 65:25:4) of the residue gave 8.9 mg of methyl oleandroside (α/β = 6:1), 27.1 mg of methyl olivoside (α/β = 5:1) and aglycon of FD-594. The aglycon was further purified by gel filtration with Sephadex LH-20 using CHCl₃·MeOH (1:1) to give 20.7 mg of aglycon 3 as an orange amorphous powder; [α]D: -295° (c 0.66, CHCl₃); UV λmax/nm in MeOH (ε): 429 (3300), 368 (11200), 281 (29100), 234 (18100) 215 (23400); IR νmax/cm⁻¹ (CHCl₃): 3451, 1654, 1625, 1549, 1516, 1490, 1477, 1460, 1056; FAB-MS m/z: 537 (M+H⁺); 1H NMR (CDCl₃) δ: 3.73 (1H, d, J=6.1 Hz), 2.72 (1H, t, J=6.1 Hz), 1.49 (3H, t, J=7.1 Hz); 13C NMR (CDCl₃) δ: 3.85 (1H, d, J=3.2 Hz), 3.40 (1H, d, J=9.0 Hz), 3.39 (1H, s), 3.33 (1H, s), 3.16 (1H, t, J=9.0 Hz), 2.48 (1H, brs), 2.27 (1H, ddd, J=3.7, 4.9, 12.7 Hz), 2.10 (1H, ddd, J=1.2, 9.0 Hz), 1.67 (1H, ddd, J=3.2, 11.7, 12.7 Hz), 1.29 (3H, d, J=6.2 Hz).

Hydrolysis of Methyl Olivoside 4
Methyl olivoside 4 (21.4 mg) was hydrolyzed in 0.1 N H₂SO₄ (1.0 ml) at 70°C for 2 hours. The solution was neutralized by addition of aq. Ba(OH)₂ and the precipitate was filtered off. The filtrate was concentrated to give 16.8 mg of olivose 6; 1H NMR (D₂O; δ/ε=5:4) δ: 5.14 (1H, dd, J=1.0, 9.3 Hz), 3.70 (2H, m), 2.93 (1H, t, J=9.5 Hz), 1.95 (1H, ddd, J=1.0, 5.1, 13.4 Hz), 1.54 (1H, ddd, J=3.7, 11.9, 13.4 Hz), 1.09 (3H, d, J=6.2 Hz); β-anomer δ: 4.74 (1H, dd, J=2.0, 9.8 Hz), 3.49 (1H, ddd, J=5.3, 9.3, 11.8 Hz), 3.25 (1H, ddd, J=7.1, 9.3 Hz), 2.88 (1H, t, J=9.3 Hz), 2.08 (1H, ddd, J=2.0, 5.3, 11.8 Hz), 1.35 (1H, dt, J=9.8, 11.8 Hz), 1.11 (3H, d, J=7.1 Hz). [α]D: +18.9° (c 0.56, H₂O); lit.4) +20° (c 1.6, H₂O).

Hydrolysis of Methyl Oleandroside 5
Methyl oleandroside 5 (8.9 mg) was hydrolyzed in 40%
Feeding Experiments

Inoculum of Streptomyces sp. TA-0256 was grown in a medium containing glucose 2%, oatmeal 2%, beef extract 0.3%, CaCO₃ 0.3%, NaCl 0.3%, MnCl₂·4H₂O 0.04%, and Fe₂(SO₄)₃·H₂O 0.04%, the pH of which was adjusted to 7.0 prior to sterilization at 121°C for 20 minutes. To the 100ml culture in a 500ml flask, 1ml of sodium acetate solution (30mg/ml for [1-¹³C]- or [2-¹³C] sodium acetate, 14mg/ml for [1, 2-¹³C₂] sodium acetate) was added repeatedly at the time of 24, 36, and 48 hours after inoculation. After 96 hours of incubation at 28°C on a rotary shaker (200 rpm), the reddish culture (2.4 liter) was centrifuged, and the mycelia were extracted twice with 500ml of acetone. After concentration of the extract in vacuo, water was added, and the mixture was further extracted with CHCl₃ at pH 5. The solvent of the extract was removed and the crude residue was purified repeatedly by chromatography with an ODS (Chromatorex DM1020T) column, first with an 85% MeOH solvent, then with 70% MeOH solvent to give red amorphous powder, which was recrystalized from CHCl₃-methanol to give 10~17mg of labeled FD-594.
