Received February 26, 1975

During our screening project to find substances biologically active to insects,1,2 we noticed that fresh leaves of avocado (Persea americana Mill.) inhibited the growth of silkworm larvae (Bombyx mori L.) by oral administration. Then we attempted the isolation of the active principle(s) in the plant and successfully obtained two components. In this paper we wish to report preliminarily our experimental result leading to structure elucidation of the compounds.

Fresh avocado leaves (3.1 kg) grown in a greenhouse at the herbary of Takeda Chemical Industries, Ltd. in Kyoto were harvested at spring of 1974 and were extracted with methanol. The extract was fractionated by the conventional method into ethyl acetate-soluble acidic, neutral and basic fractions, of which the neutral one revealed biological effect. The active fraction was applied to silica gel-celite column chromatography using benzene and benzene-ethyl acetate. An eluate with benzene containing 5% ethyl acetate was successively applied to florisil column chromatography using the same solvent system and silica acid-celite column chromatography. Thus, one active component (I) was obtained as crystals (120 mg), mp 121 ~ 122°C, and another (IIA) as an oil (1.8 g) after preparative thin-layer chromatography using silicic acid GF324 and chloroform-methanol (97: 3).

I causes direct pupation in the fourth instar larvae of silkworm without the fourth molting at the concentration of 100 ppm in the diet, while II A acts toxic to the larvae at 200 ppm.

acetylation of II\textsubscript{B} with acetic anhydride-pyridine. On the basis of the spectral data thus far mentioned, the structure of II\textsubscript{A} was deduced to be CH\textsubscript{3}COOCH\textsubscript{2}-CH(OH)-CH\textsubscript{2}-CO-CH\textsubscript{2}-C\textsubscript{16}H\textsubscript{29}.

Treatment of II\textsubscript{A} with p-toluenesulfonic acid, followed by preparative thin-layer chromatography using silicic acid GF\textsubscript{254} and hexane, afforded a new compound (II\textsubscript{D}), C\textsubscript{31}H\textsubscript{34}O, M\textsuperscript{+} 302. In the NMR spectrum of II\textsubscript{D}, signals corresponding to 2-substituted furan were observed at \( \delta \) 7.26 (1H, m), 6.25 (1H, dd, \( J=2 \) and 3 Hz) and 5.98 (1H, dd, \( J=1 \) and 3 Hz). Formation of the furan ring vigorously supports the structural assignment for the oxygenated portion in II\textsubscript{A}.

Ozonolysis of II\textsubscript{D} followed by oxidative decomposition yielded caproic acid, azelaic acid and azelaic half-aldehyde, which were identified as the forms of methyl esters with GC–MS, respectively. This indicates the locations of double bonds in the C\textsubscript{16}H\textsubscript{29} portion.

Thus, the structure of II\textsubscript{A} was established as 1-acetoxy-2-hydroxy-4-oxo-heneicosa-12,15-diene. The configuration of the double bonds in II\textsubscript{A} is considered to be cis, because the IR spectrum of the compound reveals no absorption band around 960 cm\(^{-1}\) which is characteristic of trans double bond.

Biological activities of I and II\textsubscript{A} will be reported in the near future together with details of structure elucidation of II\textsubscript{A}.
