An α-L-Arabinofuranosidase from Streptomyces purpurascens IFO 3389

Kozo Komae, Akira Kaji and Masayuki Sato

Department of Agricultural Chemistry, Kagawa University, Miki-cho, Kagawa 761-07, Japan

Received February 1, 1982

By screening 46 strains of Actinomycetes for their ability to hydrolyze arabinan, 16 strains were found to have α-L-arabinofuranosidase activity, and Streptomyces purpurascens IFO 3389 was selected as the most promising of the sixteen. An α-L-arabinofuranosidase [EC 3.2.1.55] has been highly purified from the culture fluid of this organism grown on beet arabinan as the carbon source. The molecular weight of the native enzyme was determined to be 495,000 by gel filtration and that of the subunit to be 62,000 by SDS polyacrylamide gel electrophoresis. The pH value was 3.9. The purified enzyme was active on p-nitrophenyl α-L-arabinofuranoside and arabino-oligomers, and inactive on arabinan, arabinoxylan and arabinogalactan. The optimum pH was 6.5. The enzyme was inhibited by Hg²⁺, Ag⁺ and L-arabino-γ-lactone. The values of Km and Vₘₐₓ for p-nitrophenyl α-L-arabinofuranoside were determined to be 8.2 × 10⁻⁵ M and 89.3 μmol per min per mg of protein, respectively.

Since the report by Kaji et al. in 1963 on the production of arabinosidase by Aspergillus niger, purification procedures for this enzyme have been steadily developed in our laboratory. It was purified to homogeneity and demonstrated to be α-L-arabinofuranosidase. Many fungi other than A. niger have been reported to produce a similar arabinosidase, but only one species of yeast, Rhodotorula flava, was found to be a good source of this enzyme. Bacillus subtilis elaborates α-L-arabinofuranosidase and endo-arabinase [EC 3.2.1.99] in the same culture fluid, and the two arabinosidases from Clostridium felsineum may be exo- and endo-type arabinosidases. The present paper describes the results of screening of Actinomycetes, the production and purification of α-L-arabinofuranosidase from Streptomyces purpurascens, and its properties, particularly that this arabinosidase is exclusively active on a low-molecular weight substrate.

MATERIALS AND METHODS

Organisms and cultivation. A total of 46 strains of Actinomycetes were screened for their ability to hydrolyze arabinan. The strains used here were stock cultures obtained from the Institute for Fermentation of Osaka, the Laboratory of Fermentation Physiology, Kyoto University, and the Institute of Kitazato. The organisms were cultured in a medium containing 10 g of beet arabinan, 5 g of peptone, 1 g of yeast extract and 0.05 g of MgSO₄·7H₂O in one liter of 0.05 m potassium phosphate buffer, pH 7.0. The organisms were grown in 5 ml of medium in a test tube and incubated at 28°C on a reciprocal shaker for 3 days. In the case of cultivation in flasks, the organisms were grown in 50 ml of medium in a 500-ml flask or 750 ml of medium in a 3-liter flask for 6 days. Of 6 species showing remarkable ability, S. purpurascens IFO 3389 was selected for the present investigation.

Assay methods. α-L-Arabinofuranosidase activity was assayed using beet arabinan as a substrate. The reaction mixture containing 0.5 ml of 0.5% purified beet arabinan, 0.4 ml of 0.1 M citrate-0.2 M sodium phosphate buffer, pH 6.5, and 0.1 ml of enzyme solution was incubated routinely at 30°C for 60 min. The reaction was stopped by the addition of 1 ml of 0.1 M Na₂CO₃. The reducing sugar released by the action of the enzyme was determined by the Nelson-Somogyi method using L-arabinose as a standard. When p-nitrophenyl α-L-arabinofuranoside was used as substrate, a reaction mixture containing 0.5 ml of 1 mM substrate, 0.4 ml of 0.1 M citrate-0.2 M sodium phosphate buffer, pH 6.5, and 0.1 ml of enzyme solution was
incubated at 30°C for 10 min. The reaction was stopped and the amount of p-nitrophenol released was determined spectrophotometrically at 400 nm. The enzymatic activity on p-nitrophenyl a- and b-D-galactopyranosides was assayed under the same conditions. One unit of enzyme activity was defined as the amount of enzyme which liberates 1 μmol of L-arabinose or p-nitrophenol per min under the above conditions.

The amount of protein in the enzyme solution was estimated from the absorbance at 280 nm. The crystalline a-L-arabinofuranosidase, which had been prepared in our laboratory from the culture fluid of A. niger, was used as a standard in the protein assay. The degree of cell growth was measured by weighing the cells after washing and drying them. Identification of the reaction products was carried out by paper chromatography. Ethanol was added to the reaction mixture and the precipitate was removed by centrifugation. The supernatant fluid was evaporated and the residue dissolved in deionized water. Then the dissolved solution was spotted on a paper and developed descendingly with a solvent system of n-butanol-pyridine-water = 6:4:3. The sugars were visualized with alkaline AgNO3 or aniline hydrogen phthalate reagent.

Purification of enzyme. The centrifuged culture filtrate, 45 liters, was made to 50% saturation with respect to ammonium sulfate and stood overnight. The resulting precipitate was removed by centrifugation at 9,600 x g. The supernatant was made to 70% saturation, and the precipitate was collected and dialyzed against deionized water. The enzyme was eluted stepwisely with 0.1, 0.2 and 0.5 M NaCl in the same buffer. Fractions rich in the arabinosidase thus obtained were purified as described previously.11 Arabinoxylan, 1,5-arabinan and wheat bran extract were also prepared as described previously.11 Arabino-biose and triose (α-1,5-linkage) were prepared by Mr. Yoshihara from 1,5-arabinan with endo-arabinase as reported previously.6 Phenyl β-D-arabinoside and p-nitrophenyl glycosides were purchased from Koch-Light Laboratories, Ltd.

Electrophoresis. Polyacrylamide gel electrophoresis (7.5%) was performed according to the method of Davis12 with pH 8.3 buffer system. SDS-polyacrylamide gel electrophoresis was carried out according to the procedure of Weber and Osborn13 with a polyacrylamide (12.5%) slab gel containing 0.1% sodium dodecyl sulfate. Protein was stained with 0.1% Coomassie Brilliant Blue R. Gels were destained in 7% acetic acid. Isolelectric focusing electrophoresis was carried out with carrier ampholine (pH 4–6) by the method of Vesterberg and Svensson14 with the small scale column designed by Doi and Ohtsuru.15

RESULTS

1. Screening

By screening 46 strains of Actinomycetes for their ability to hydrolyze arabinan, 16 strains were found with enzymatic activity. Six strains with significant activity are listed in Table I. S. purpurascens IFO 3389 was selected as a suit-

* Beet arabinan was used as substrate in the enzyme assay.

An arabinosidase from *Streptomyces purpurascens* was found in the culture fluid when beet arabinan was used, and the activity was estimated to be 10.5 m units per mg of dry cells. Arabinose was also a fairly good carbon source and arabinosidase activity was 5.9 m units per mg of dry cells. Pectin, soy bean powder, wheat bran extract, gum arabic and galactose were poor carbon sources. Soluble starch was not effective for the production of arabinosidase activity.

3. Purification of enzyme

The crude enzyme solution, 1.4 liters, was poured onto a column of DEAE-cellulose. The results of the chromatography are shown in Fig. 1. Arabinosidases were eluted as peaks I, II and III. The ratio of the enzymatic activity toward p-nitrophenyl α-L-arabinofuranoside to that on arabinan in peak III is larger than those of peaks I and II. The arabinosidases in the latter two peaks were the same type as the reported α-L-arabinofuranosidase from various organisms, that is to say, these arabinosidases were active not only on p-nitrophenyl α-L-arabinofuranoside but also on arabinan. Thus, the enzyme in peak III was further purified by column chromatography on QAE-Sephadex A-50. The arabinosidase was eluted with 0.2 to 0.6 M NaCl in 0.01 M citrate–0.02 M sodium phosphate buffer, pH 7.5. It was highly active on p-nitrophenyl α-L-arabinofuranoside, and slightly active on arabinan. After the active fractions were combined, dialyzed and concentrated, the enzyme was further purified by gel filtration on Sepharose 6B. The enzyme solution was poured onto a column of hydroxylapatite, and the activity was, subsequently, recovered in two peaks (Fig. 2). The enzyme in the minor peak was different from the enzyme in major one in pI.

The enzyme solution in the main peak was dialyzed and the dialyzed solution was concentrated. The solution ran through a column of Sepharose 6B and the activity curve was parallel with the curve of protein in a single peak. The results of the overall purification procedures are summarized in Table II. The enzyme was purified 120-fold. A single band in

* p-Nitrophenyl α-L-arabinofuranoside was used as substrate in the enzyme assay.

Fig. 3 demonstrates the homogeneity of the purified α-L-arabinofuranosidase.

4. Properties of the purified enzyme

(1) Molecular weight. The molecular weight of α-L-arabinofuranosidase was determined to be 495,000 by gel filtration on Sepharose 6B. The molecular weight of the subunit was calculated to be 62,000 by SDS polyacrylamide gel electrophoresis for which the standard proteins were thyroglobulin, ferritin, catalase, phosphorylase, albumin and lactate dehydrogenase (Fig. 4). The native enzyme may consist of 8 subunits.

(2) Isoelectric point. The pI value was determined to be 3.9 by isoelectric focusing electrophoresis.

(3) Effect of pH on the activity of the purified enzyme. The effect of pH on the activity of the purified enzyme is shown in Fig. 5. The optimum pH for the enzymatic activity is 6.5.

(4) Substrate specificity of the purified enzyme. As shown in Table III, the enzyme was remarkably active on p-nitrophenyl α-L-arabinofuranoside. After the purified enzyme had acted on arabino-biose and triose, re-

a Concentration of substrate in the reaction mixture.
b Micromoles per minute per milligram of enzyme protein.

The enzyme was inactive on arabinan, arabinoxylan, arabinogalactan, p-nitrophenyl β-D-galactopyranoside, phenyl β-L-arabinopyranoside and the following p-nitrophenyl glycosides: α-D-galactopyranoside, α- and β-D-glucopyranosides, α- and β-D-xylopyranosides, α-L-fucopyranoside, α-D-mannopyranoside and N-acetyl β-D-glucosaminide.

(5) Inhibitory studies. After the enzyme was preincubated in 0.1 M citrate-0.2 M sodium phosphate buffer (pH 6.5) containing the salts and inhibitors for 10 min, the substrate was added to the enzyme solution and the enzymatic activity was determined. Blank tests were run with boiled enzyme. The purified enzyme was completely inhibited by Hg²⁺ and Ag⁺ at 1 mM. It was also potently inhibited by L-arabonic-γ-lactone (10 mM).

(6) The values of Km and Vmax. The Michaelis constant (Km) and maximum velocity (Vmax) of the purified enzyme for p-nitrophenyl α-L-arabinofuranoside were calculated to be 8.2 x 10⁻⁵ M and 89.3 µmol per mg of protein, respectively, from Lineweaver-Burk plots at pH 6.5 and 30°C.

DISCUSSION

The present paper is the first to describe a wide screening of Actinomycetes for their ability to produce arabinosidase. About one third of the type cultures tested had arabinosidase activity. As reported elsewhere,¹⁶ we isolated...
150 strains of wild-type Actinomycetes from soil in Kagawa Prefecture on a medium containing beet arabinan as the sole carbon source. From them about 50 strains were selected as having arabinosidase activity. Most of these organisms seemed to belong to Streptomyces. It was, therefore, shown that Actinomycetes with arabinosidase activity occur frequently, especially of the genus Streptomyces.

Monomeric as well as polymeric arabinose was a good carbon source for the production of arabinosidase by S. purpurascens IFO 3389, a typical enzyme producer. Similar results were observed for the production of the same enzyme by fungi such as A. niger and Botrytis cinerea, while for production by R. flava arabinose was not a good carbon source. Therefore, S. purpurascens appears to be similar to fungi rather than to yeast in this regard.

α-L-Arabinofuranosidases produced by various fungi, i.e. A. niger, C. rolfsii, B. cinerea, Sclerotinia libertiana, Botrytis fabae, Sclerotinia fructigena, Myrothecium verrucaria, R. flava, or bacteria, i.e. B. subtilis, Streptomyces massaspoeus, are active on high-molecular weight substrates such as beet arabinan, arabinoyxylan and arabinogalactan, as well as on low-molecular weight synthetic substrates, hydrolyzing 1,3- and 1,5-arabinosyl linkages.

The authors have found, while screening a great number of Actinomycetes, that one component of arabinosidases of S. purpurascens IFO 3389, unlike the arabinosidase mentioned above, is inactive on polymers on incubation for 6 hr at 30°C, though active on p-nitrophenyl α-L-arabinofuranoside and arabino-oligomers. On the basis of this specificity, it was concluded that the highly purified arabinosidase of S. purpurascens is a new type of α-L-arabinofuranosidase [EC 3.2.1.55] in regard to its substrate specificity. As the organism produced a great deal of this arabinosidase in the culture fluid, it is a good source of the enzyme.

In the present studies, an arabinosidase produced by S. purpurascens was found to be exclusively active on a low-molecular weight substrate, but it may be, conversely, that an arabinosidase exclusively active on a high-molecular weight substrate, such as beet arabinan, can be produced by Bacillus subtilis and Erwinia carotovora, according to recent work in our laboratory (unpublished).

Acknowledgment. We thank Mr. O. Yoshihara for his helpful work.
