Group A streptococcus is a bacterium that resides in the throat and skin and causes respiratory infection and occasionally glomerulonephritis and rheumatic fever. Streptolysin O (SLO), produced by Streptococcus pyogenes (S. pyogenes), binds to the cell membrane, particularly to that of white and red blood cells, and is toxic to the cells and tissue. In this study, we evaluated the inhibitory activity of water-soluble polyphenols in olives (Olea europaea) against SLO-induced hemolysis. Hydroxytyrosol inhibited SLO-induced hemolytic activity, and the amount required for 50% inhibition of hemolysis was 1.30 µg. These findings suggest that the water-soluble polyphenols contained in olives have inhibitory activity against SLO-induced hemolysis.

Key words: Streptococcus pyogenes / Olea europaea / Streptolysin O / Hydroxytyrosol.
(21,130 x g, 15 min), and 2 ml of the water-soluble components were collected. The samples were stored at -80°C.

Hemolytic activity was spectrophotometrically determined using a 50% endpoint titration (Kusama et al., 1958). With reference to this method of Kusama et al. (1958), we established a microplate method with the amounts of reagents and sample reduced to 1/10 the scale of the original method. Pure SLO (Wako Pure Chemical Industries, Ltd., Osaka, Japan) was diluted on a 0.1 log-unit dilution scale with phosphate-buffered saline (PBS, pH 6.5) supplemented with 2-mercaptoethanol (2-ME) and bovine serum albumin. Test samples (olives, hydroxytyrosol (Wako Pure Chemical Industries)) were added in the microplate (Sumitomo Bakelite Co. Ltd, Tokyo, Japan), and then 50 µl of a 2.5%-suspension of rabbit erythrocytes (Nippon Bio-Supp. Center, Tokyo, Japan) in PBS was added to 150 µl of solution. After incubation at 37°C for 1 h, tubes were centrifuged, and absorbance of the supernatant was measured at 510 nm against a blank containing the diluent.

Activity was expressed as the 50% hemolytic dose (HD50) per ml. To determine hemolytic efficiency (HE), the % hemolysis was calculated for each tube and converted into a probit. A rectilinear curve was obtained by plotting the probit against the log of the hemolysin dose. HE was obtained from this curve using the formula: 

$$HE = \frac{NPxy - PxPy}{NPx^2 - (Px)^2}$$

where x is the log of the hemolysin dose, y is the % lysis in the probits, and N is the number of points in the rectilinear curve.

The hemolytic potencies were 1.51 x 10^3 ± 96.2 HD50/ml (CV 6.8%), 1.22 x 10^3 ± 124.3 HD50/ml (CV 15.2%), and 1.01 x 10^3 ± 102.9 HD50/ml (CV 10.2%) after addition of 0.5, 1.0, and 1.5 µl of immature olive extract, respectively. The inhibition rates were 22.9%, 34.2%, and 47.5%, respectively (Fig.1), and 1.47 µl of extract was required for 50% inhibition of hemolysis. The hemolytic potencies were 2.12 x 10^3 ± 265.7 HD50/ml (CV 12.8%), 1.56 x 10^3 ± 114.2 HD50/ml (CV 26.2%), and 1.26 x 10^3 ± 95.2 HD50/ml (CV 8.1%) after addition of 0.5, 1.0, and 1.5 µg of hydroxytyrosol, respectively. The inhibition rates were 22.9%, 34.2%, and 61.8%, respectively (Fig.2), and 1.30 µg of hydroxytyrosol inhibited SLO-induced hemolytic activity, with 1.30 µg required for 50% inhibition of hemolysis. These findings suggest that water-soluble polyphenols contained in olives have inhibitory activity. Olive extracts also inhibited the hemolytic activity of SLO, with 1.47 µl and 1.78 µl of immature and ripe fruit.

The samples were stored at -80°C.

Hemolytic activity was spectrophotometrically determined using a 50% endpoint titration (Kusama et al., 1958). With reference to this method of Kusama et al. (1958), we established a microplate method with the amounts of reagents and sample reduced to 1/10 the scale of the original method. Pure SLO (Wako Pure Chemical Industries, Ltd., Osaka, Japan) was diluted on a 0.1 log-unit dilution scale with phosphate-buffered saline (PBS, pH 6.5) supplemented with 2-mercaptoethanol (2-ME) and bovine serum albumin. Test samples (olives, hydroxytyrosol (Wako Pure Chemical Industries)) were added in the microplate (Sumitomo Bakelite Co. Ltd, Tokyo, Japan), and then 50 µl of a 2.5%-suspension of rabbit erythrocytes (Nippon Bio-Supp. Center, Tokyo, Japan) in PBS was added to 150 µl of solution. After incubation at 37°C for 1 h, tubes were centrifuged, and absorbance of the supernatant was measured at 510 nm against a blank containing the diluent.

Activity was expressed as the 50% hemolytic dose (HD50) per ml. To determine hemolytic efficiency (HE), the % hemolysis was calculated for each tube and converted into a probit. A rectilinear curve was obtained by plotting the probit against the log of the hemolysin dose. HE was obtained from this curve using the formula:

$$HE = \frac{NPxy - PxPy}{NPx^2 - (Px)^2}$$

where x is the log of the hemolysin dose, y is the % lysis in the probits, and N is the number of points in the rectilinear curve.

The hemolytic potencies were 1.51 x 10^3 ± 96.2 HD50/ml (CV 6.8%), 1.22 x 10^3 ± 124.3 HD50/ml (CV 15.2%), and 1.01 x 10^3 ± 102.9 HD50/ml (CV 10.2%) after addition of 0.5, 1.0, and 1.5 µl of immature olive extract, respectively. The inhibition rates were 22.9%, 34.2%, and 47.5%, respectively (Fig.1), and 1.47 µl of extract was required for 50% inhibition of hemolysis. The hemolytic potencies were 2.12 x 10^3 ± 265.7 HD50/ml (CV 12.8%), 1.56 x 10^3 ± 114.2 HD50/ml (CV 26.2%), and 1.26 x 10^3 ± 95.2 HD50/ml (CV 8.1%) after addition of 0.5, 1.0, and 1.5 µg of hydroxytyrosol, respectively. The inhibition rates were 22.9%, 34.2%, and 61.8%, respectively (Fig.2), and 1.30 µg of extract was required for 50% inhibition of hemolysis. The hemolytic potencies were 1.96 x 10^3 ± 108.1 HD50/ml, 1.41 x 10^3 ± 98.4 HD50/ml, and 8.14 x 10^2 ± 42.8 HD50/ml after addition of 0.5, 1.0, and 1.5 µg of hydroxytyrosol, respectively, and the inhibition rates were 9.8%, 34.2%, and 61.8%, respectively (Fig.3). The amount required for 50% inhibition of hemolysis was 1.30 µg.

Hydroxytyrosol inhibited SLO-induced hemolytic activity, with 1.30 µg required for 50% inhibition of hemolysis. These findings suggest that water-soluble polyphenols contained in olives have inhibitory activity. Olive extracts also inhibited the hemolytic activity of SLO, with 1.47 µl and 1.78 µl of immature and ripe fruit.
extracts required for 50% inhibition of hemolysis, respectively. The greater inhibition by immature fruit extract is consistent with the respective polyphenol contents of 0.61 and 0.36 mg/g in olive oil prepared from immature and ripe fruits of the same variety (Mission) (Shibasaki, 2000). The water-soluble components of immature fruit contain abundant polyphenols, as well as oil components, and this may increase the inhibitory activity. We measured the concentration of hydroxytyrosol using HPLC with Shiseido Co., Ltd. The concentration of hydroxytyrosol was 0.44 ± 0.03 mg/g in immature olives and 0.32 ± 0.02 mg/mL in ripe olives.

The antioxidative action of tea catechins (epicatechin, epigallocatechin, epicatechin gallate, and epigallocatechin gallate) requires the presence of catechol, pyrogallol, and galloyl groups, and is dependent on the configurations in these groups (Toda et al., 1990). A hydroxytyrosol contained in the water-soluble component of the olive fruit may also influence the configuration of SLO. Hydroxytyrosol (C_8H_10O_3) possesses only one catechol group.

*S. pyogenes* infection results in general symptoms of respiratory disease caused by airborne droplet infection and food poisoning, and may also lead to the development of serious symptoms of fulminating hemolytic streptococcal infection. This infectious disease is frequently fatal, with 57 fatal cases among a total of 143 patients in Japan in 2012 (Streptococcal infections in Japan, April 2006-2011. IASR., 33, 209-210, 2012). In the case of the sudden death of a mother and fetus, high SLO production induced severe hemolytic anemia and pulmonary hemorrhage, and was closely involved in fetal cardiac arrest (Kanno et al., 2011).

Hemolysin-producing bacteria other than *S. pyogenes* include *Staphylococcus aureus*, *Vibrio parahaemolyticus*, *Vibrio cholera*, and *Clostridium perfringens*, and olives are also likely to have hemolysin inhibitory activity against these bacteria (Toda et al., 1990). No inhibitory effect of tea catechins on the hemolytic activity of the δ toxin of *Staphylococcus aureus*, heat-resistant hemolysin Vp-TDH of *Vibrio parahaemolyticus*, or cholera toxin was observed, and the effect was similar to that of the negative control. However, hemolytic activity was noted for catechins and their structural analogs, suggesting that the different result was due to a structural difference (Toda et al., 1990). We are planning to investigate the action of water-soluble polyphenols of olives against the hemolysin produced by other bacteria.

In the current study, immature and ripe olive extracts showed inhibitory activity against SLO-mediated hemolysis produced by *S. pyogenes*. Hydroxytyrosol, which is a water-soluble polyphenol found abundantly in olives, also showed hemolysin inhibition.
