Inhibitory Effects of Korean Red Ginseng and Its Genuine Constituents Ginsenosides Rg3, Rf, and Rh2 in Mouse Passive Cutaneous Anaphylaxis Reaction and Contact Dermatitis Models

Eun-Ah Bae,a Myung Joo Han,a Yong-Wook Shin,b and Dong-Hyun Kim*a,b

Received November 16, 2005; accepted April 28, 2006

The inhibitory effects of the Korean red ginseng (steamed root of Panax ginseng C.A. Meyer, family Araliaceae) saponin fraction (KRGS) and its constituents ginsenosides Rg3, Rf, and Rh2 in mouse passive cutaneous anaphylaxis (PCA) and contact dermatitis models were measured. Orally administered KRGS and its genuine ginsenosides potently inhibited the PCA reaction induced by IgE. However, when these ginsenosides were intraperitoneally administered, ginsenoside Rh2 showed the most potent inhibition. The ginsenoside Rh2 also the most potently inhibited the β-hexosaminidase release from RBL-2H3 cells induced by IgE with antigen. KRGS administered topically at a dose of 0.1% suppressed ear swelling in an oxazolone-induced mouse contact dermatitis model by 38.8%. Its constituents ginsenosides Rg3, Rf, and Rh2 at a concentration of 0.05% also potently suppressed mouse ear swelling by 47.5%, 34.8%, and 49.9% at 16 d, respectively. These ginsenosides also significantly reduced mRNA expression levels of cyclooxygenase (COX)-2, interleukin (IL)-1β, tumor necrosis factor-α and interferon-γ induced by oxazolone applied to mouse ears. However, the ginsenosides, except for ginsenoside Rh2, almost did not notably reduce IL-4 levels. The ginsenoside Rh2 also potently inhibited COX-2 and inducible NO synthetase protein expression in lipopolysaccharide-stimulated RAW264.7 cells. Based on these findings, KRGS and its ginsenosides are suggested to improve atopic and contact dermatitis by regulating expression of cytokines.

Key words Korean red ginseng; ginsenoside Rf; ginsenoside Rh2; antiallergic activity; antipsoriatic activity

Korean red ginseng (KRG, the steamed root of Panax ginseng C.A. Meyer, family Araliaceae) is frequently used as a crude substance taken orally in Asian countries as a traditional medicine. The major components of raw ginseng are ginsenosides, which contain an aglycone with a dammarane skeleton. Many types of saponins, such as ginsenosides Rb1, Rb2, Re, and Rf, have been isolated. The ginsenosides Rg3, Rf, and Rh2 are genuine saponins in KRG and heat-processed ginseng. Ginsenosides Rg3 and Rh2 were produced from protopanaxadiol ginsenosides by steaming to prepare KRG.

Psoriasis is a chronic inflammatory skin disorder. Psoriasis patients have been shown to have interferon (IFN)-γ producing Th1 bias in lesion skin and peripheral blood and are thought to develop cytokine networks of Th1 cells, resulting in keratinocyte hyperplasia and angiogenesis. Cyclooxygenase (COX)-2 is also induced in angiogenesis-related diseases such as rheumatoid arthritis and psoriasis. Fujii et al. developed an oxazolone-induced animal model of experimental psoriasis. This psoriatic animal model is a chronic inflammation model and significantly induces the expression levels of COX-2 and inducible NO synthase (iNOS) in monocytes and macrophages and IFN-γ and interleukin (IL)-4 in Th cells. The ginsenosides have been reported to show various biological activities including antiinflammatory activity, antiallergic, endothelium-independent aorta relaxation, and antitumor effects. Tachikawa et al. reported that ginsenoside Rg3 suppressed histamine release from mast cells due to stimulation with compound 48/80 in vitro, and Ro et al. reported that ginsenosides Rb1 and Re partly inhibited the release of histamine and leukotrienes during the activation of guinea pig lung mast cells in vitro. We also reported the antiallergic and antiinflammatory effects of ginsenoside Rh1, antiallergic and passive cutaneous anaphylaxis (PCA) reaction-inhibitory effects of compound K, and antiallergic effects of ginsenoside Rh2. However, the antiallergic and antipsoriatic effects of KRG and genuine ginsenoside Rh2 have not been thoroughly studied. We therefore investigated the PCA reaction-inhibitory and antiallergic and antipsoriatic effects of the KRG saponin fraction (KRGS) and its constituents ginsenosides Rg3, Rf, and Rh2.

MATERIALS AND METHODS

Materials p-Nitrophenyl-N-acetyl-β-D-glucosaminide, Freund’s complete adjuvant, anti-dinitrophenol (DNP)-IgE, DNP-human serum albumin (HSA), lipopolysaccharide (LPS), Evans blue, disodium cromoglicate (DSCG), trichloroacetic acid, betamethasone, and azelastine were purchased from Sigma Chemical Co. (St. Louis, MO, U.S.A.). KRG water extract, ginsenoside Rf, and ginsenoside Rh2 were donated by KT&G (Seoul, Korea). KRGS and ginsenoside Rg3 were prepared according to our previous method. KRGS, which is the BuOH fraction of KRG, contains ginsenosides Rb1 (16.3%), Rf (7.4%), Rg3 (4.6%), and Rh2 (0.1%) as the main constituents.

Assay of Antiallergic Activity in the RBL 2H3 Cell Line The inhibitory activity of KRGSs and its genuine ginsenosides against the release of β-hexosaminidase from RBL-2H3 cells was evaluated according to the method of Choi et al. RBL-2H3 cells were grown in Dulbecco’s modified Eagle medium supplemented with 10% fetal bovine serum and t-glutamine and split every 3 d. Before the experiment, cells were dispensed into 24-well plates (5×105 cells per well) using medium containing 0.5 μg/ml of mouse monoclonal IgE and incubated overnight at 37°C in 5% CO2 for sensitization. The cells were washed with 500 μl of siragian buffer (pH 7.2, NaCl 119 mm, KCl 5 mm, MgCl2 0.4 mm,
piperazine-N,N-bis(2-ethanesulfonic acid) 25 mM, NaOH 40 mM and incubated in 160 μl of siraganian buffer containing glucose 5.6 mM, CaCl₂ 1 mM, and 0.1% bovine serum albumin for an additional 10 min at 37 °C. Then cells were exposed to 40 μl of test agents for 20 min, followed by the treatment with 20 μl of antigen (DNP-HSA, 1 μg/ml) for 10 min at 37 °C to activate cells to evoke allergic reactions. The reaction mixture was centrifuged at 800 g for an additional 10 min at 37 °C. Then cells were Expanded 25 μl aliquots of supernatant were transferred to 96-well plates and incubated with 25 μl of substrate (p-nitrophenyl-N-acetyl-β-d-glucosaminide 1 mM) for 1 h at 37 °C. The reaction was stopped by adding 200 μl of Na₂CO₃/NaHCO₃ 0.1 M (pH 10.5). The absorbance was measured with an ELISA microplate reader at 405 nm.

Animals Male and female ICR mice (20—25 g) were supplied by the Orient Charles River Experimental Animal Breeding Center (Seoul, Korea). All animals were housed in wire cages and fed with standard laboratory chow (Orient Charles River Feed Production Co., Seoul, Korea) and water ad libitum. All procedures relating to animals and their care were carried out according to the international guidelines on Principles of Laboratory Animal Care (NIH publication no. 85-23, revised 1985).

PCA Reaction The IgE-dependent cutaneous reaction was measured according to the previous method of Katayama et al.²⁰ Male ICR mice (25—30 g) were injected intradermally with 10 μg of anti-DNP IgE into each of two dorsal skin sites that had been shaved 48 h earlier. The sites were outlined with a water-insoluble red marker. Forty-eight hours later, each mouse received an injection of 1 ml of 1% oxazolone in a mixture of acetone and 0.6 N phosphoric acid (13 : 5), the reaction was stopped by adding 200 μl of test agents for 20 min, followed by the addition of 1 ml of 1.0 N KOH and 4 ml of a mixture of acetone and 0.6 N phosphoric acid (13 : 5), the amount of dye was determined colorimetrically (absorbance at 620 nm).

Contact Hypersensitivity Oxazolone-induced dermatitis was measured according to the method of Fujii et al.²¹ Female ICR mice were sensitized by the application of 100 μl of 1.5% oxazolone in ethanol to the abdomen. Then a total of 20 μl of 1% oxazolone in a mixture of acetone and olive oil (4 : 1) was applied to both sides of the mouse ear every 3 d starting from 7 d after sensitization. Ear thickness was measured using a Digmatic Micrometer (Mitsutoyo Co., Tokyo, Japan). Test agents were applied in a total volume of 20 μl to both sides of the ear 30 min before and 3 h after each application of oxazolone.

RT-PCR Analysis Ear tissue extraction for RT-PCR analysis was performed using the modified method of Chi et al.²² Briefly, ears were excised 6 h after the last application of oxazolone, frozen in liquid nitrogen, and homogenized with a mortar and pestle prechilled in liquid nitrogen. Total RNA was extracted using TRI Reagent (Molecular Research Center, Inc., Cincinnati, OH, U.S.A.) according to the manufacturer’s instructions and treated with RNase-free DNase. The concentration of RNA was determined by measuring the absorbance at 260 and 280 nm, and tissue were stored at −70 °C until RT-PCR analysis. RT-PCR was performed with AccPower RT/PCR Premix (Bioneer, Seoul, Korea). The primers were designed as described in the UniSTS database: COX-1, forward primer 5'-CTTTATCCTCCAGATT-GTG-3 and reverse primer 5'-GTCAATTCTGTGAC-CGG-3 (product size 231 bp); COX-2, forward primer 5'-TGATTCGCCACAGTCAAGAC-3 and reverse primer 5'-GTGCTCCCCAGACAGGTG-3 (product size 146 bp); IL-1β, forward primer 5'-ATGGCAACTGTCCTG-3 and reverse primer 5'-GCGATTTATTTGCATCG-3 (product size 144 bp); IL-4, forward primer 5'-CCGATTATGTGTAATTTCCTA-TGCTG-3 and reverse primer 5'-GGCCAAATCGACCCACTC-TCTTCCAG-3 (product size 111 bp); tumor necrosis factor (TNF)-α, forward primer 5'-GATTTATTTTAAAGCGAGATATC-3 and reverse primer 5'-CATCCTAAGTCTCA ACCAGATCT-3 (product size 206 bp); glyceraldehyde-3-phosphate dehydrogenase (GAPDH), forward primer 5'-ACCACGTTCATGCATCAC-3 and reverse primer 5'-TCACACACCTGTGCTGGT-3 (product size 452 bp). The amplification was performed at 94 °C for 30—60 s, and 49—62 °C for 30—40 s, and 72 °C for 30—60 s with 30 cycles for COX-1, IL-1β, TNF-α and GAPDH, and 32 cycles for other genes, in 20 μl of reaction mixture. The RT-PCR products were electrophoresed on 2% agarose gel in Tris–borate–ethylenediaminetetraacetic acid (TBE) buffer, stained with ethidium bromide, and photographed under UV light. The mRNA of GAPDH was used as an internal control. The signal intensity of each RT-PCR product was estimated using a Shimadzu 9301-PC scanner (Shimadzu Co., Tokyo, Japan).

Culure of RAW264.7 Cells and Immunoblot Analysis Immunoblot analyses of iNOS, COX-2, and nerve factor-kappaB (NF-κB) were performed according to the method of Ishihara et al.²³ The RAW264.7 cells were plated in 60 mm culture dishes (3×10⁶ cells), test agents and LPS (1 μg/ml) added to the culture medium, and the cells were incubated at 37 °C for 6—20 h. The cells were lysed on ice for 15 min in a hypotonic buffer, containing Tris 10 mM (pH 8.0), MgCl₂ 1.5 mM, dithiothreitol 1 mM, 0.1% NP-40, peptatin A 5 μg/ml, and aprotinin 5 μg/ml and centrifuged at 12000×g for 4°C for 15 min. The supernatant was used as the cytosol fraction for the immunoblot assays for iNOS and COX-2 protein expression. The pelleted nuclei fractions for the immunoblot assays of NF-κB protein expression were resuspended in the extraction buffer containing Tris 10 mM (pH 8.0), KCl 50 mM, NaCl 300 mM, dithiothreitol 1 mM, peptatin A 5 μg/ml, and aprotinin 5 μg/ml and then lysed on ice for 30 min. The lysed nuclei fraction was centrifuged at 12000×g and 4°C for 30 min. Protein expression levels of COX-2, iNOS, NF-κB and β-actin in the cell lysates (40 μg) were analyzed using the above immunoblot method.

Statistics All the data are expressed as the mean±standard error, and statistical significance was analyzed by one-way ANOVA followed by the Student–Newman–Keuls test.

RESULTS

Inhibition by KRGS and Its Ginsenosides of β-Hexosaminidase Release from RBL-2H3 Cells To investigate
whether KRGS and its genuine ginsenosides possess antiallergic activity, we examined their inhibitory effects against β-hexosaminidase release (degranulation) from RBL-2H3 cells induced by IgE with antigen (Table 1). Ginsenosides Rf and Rh2 potently inhibited β-hexosaminidase release from RBL-2H3 cells induced by IgE, with IC<sub>50</sub> values of 0.08 and 0.03 nm, respectively, and the results were comparable those of azelastine. However, KRGS and ginsenoside Rg3 only weakly inhibited the degradation of RBL-2H3 cells.

**Inhibition of the PCA Reaction by KRGS and Its Ginsenosides**

The PCA reaction in sensitized mice was induced by the intradermal injection of DNP-HSA, KRGS or its constituents were administered orally or intraperitoneally 60 min prior to challenge with DNP-HSA antigen, and their inhibitory potency against the PCA reaction was measured (Table 2). KRGS orally administered at a dose of 500 mg/kg potently inhibited the PCA reaction. Orally and administered intraperitoneally ginsenosides Rf, Rg3, and Rh2 also significantly inhibited the PCA reaction. The inhibitory potency of these ginsenosides intraperitoneally administered at a dose of 25 mg/kg was greater than that when orally administered. The inhibitory effects of these ginsenosides were more potent than that of DSCG, but was inferior to that of azelastine. However, KRGS and ginsenoside Rg3 only weakly inhibited the PCA reaction and that in control mice were 0.21 and 0.75 m, respectively.

**Inhibition by KRGS and Its Ginsenosides of Ear Swelling in Oxazolone-Induced Mouse Ear Dermatitis**

In the preliminary experiment, KRGS suppressed the swelling of oxazolone-induced mouse ear dermatitis after topical administration (Fig. 1). Therefore we also measured the effects of its genuine saponin ginsenosides Rf, Rg3, and Rh2. Oxazolone applied to the ears of sensitized mice caused erythema (reddening of the skin), edema, and/or induration, and sometimes abrasion. When the ear thickness was measured as an index of skin inflammation, it increased with repeated application, and reached the maximum 16 d after sensitization. Dermatitis persisted for 2 d and then slowly declined. Betamethasone used as a positive agent at the concentration of 0.05% suppressed ear swelling by 75% at 16 d. The ginsenosides Rf, Rg3, and Rh2 at a concentration of 0.05% also inhibited the swelling after oxazolone sensitization at 16 d by 34.8%, 47.5%, and 49.9%, respectively, compared with oxazolone-alone control group. For histopathologic analysis, we excised ears at 16 d and stained them with hematoxylin–eosin (Fig. 2). The ears sensitized with oxazolone-alone control group. For histopathologic analysis, we excised ears at 16 d and stained them with hematoxylin–eosin (Fig. 2).

zolone swelled markedly and sometimes showed abrasion. Oxazolone-sensitized ears could not be stained throughout the entire section. However, the ginsenosides reduced the thickness of swollen ears after the application of oxazolone. The ginsenosides also improved the abrasion and swelling. Nevertheless, the effects of these ginsenosides were inferior to that of betamethasone.

Effects of KRGS and Its Ginsenosides on mRNA Expression Levels of COXs and Cytokines in Oxazolone-Induced Mouse Ear Dermatitis

The effect of KRGS and its genuine ginsenosides on mRNA expression levels of COX-1, COX-2, and some cytokines in mouse ear dermatitis induced by oxazolone was investigated using RT-PCR analysis (Fig. 3). Oxazolone significantly induced the mRNA expression of COX-2. However, it did not induce that of COX-1. When oxazolone-treated mice were treated with KRGS and its ginsenosides, these agents did not affect the COX-1 mRNA expression. However, KRGS and its ginsenosides inhibited mRNA expression levels of COX-2. Among them, ginsenoside Rh2 most potently inhibited the mRNA expression of COX-2. Oxazolone significantly induced mRNA expression of TNF-α and IL-1β, which are produced by macrophages or monocytes, and IFN-γ and IL-4, which are produced by Th1 and Th2 cells. KRGS and its ginsenosides potently inhibited mRNA expression of IL-1β, IFN-γ, and TNF-α, although that of IL-4 was only weakly inhibited. Among these ginsenosides, ginsenoside Rh2 exhibited the most potent inhibition.

Effects of KRGS and Its Ginsenosides on iNOS and COX-2 Protein Expression and NF-κB Activation in LPS-Induced RAW264.7 Cells

Immunoblot analysis was also used to determine whether KRGS could affect the protein expressions of iNOS and COX-2 (Fig. 4). Stimulation of RAW 264.7 cells with LPS not only increased the expression levels of iNOS and COX-2 proteins, but also increased the activated transcription factor NF-κB, p65, in the nuclei of the cells. KRGS only slightly reduced iNOS and COX-2 protein levels, although KRGS weakly inhibited the activation of transcription factor NF-κB in the nuclei of RAW264.7 cells stimulated with LPS. The effects of its ginsenosides were also investigated. The ginsenosides inhibited iNOS and COX-2 protein expression and reduced activated NF-κB p65.

Fig. 3. Effects of KRGS and Its Ginsenosides on COX-1, COX-2, IL-1β, IL-4, INF-γ, TNF-α, and GAPDH mRNA Expression Levels in Oxazolone-Induced Mouse Ear Dermatitis

(A) RT-PCR products; (B) relative density (%) of RT-PCR products [COX-1, COX-2, IL-1β (IL-1), INF-γ (IFN), or TNF-α (TNF)/GAPDH]. Mouse ears were excised 72 h after the final application of oxazolone and stained with hematoxylin–eosin. As a negative control, mice were sensitized with 1.5% oxazolone alone on the abdomen followed by no application to the ear (1). 1% oxazolone and vehicle (ethanol) was applied to both sides of the ear every 3 d starting from 7 d after sensitization (2). 1, normal control; 2, treated with oxazolone alone; 3, treated with 0.1% KRGS with oxazolone; 4, treated with 0.05% ginsenoside Rf and oxazolone; 5, treated with 0.1% ginsenoside Rf and oxazolone; 6, treated with 0.05% ginsenoside Rh2 and oxazolone; 7, treated with 0.05% ginsenoside Rh3 and oxazolone; 8, treated with 0.05% ginsenoside Rh2 and oxazolone; 9, treated with 0.1% ginsenoside Rh2 and oxazolone; 10, treated with 0.05% betamethasone and oxazolone.
in the nuclei fraction induced by LPS. Ginsenoside Rh2 is the most potent inhibitor of the protein expression of iNOS and COX-2 and reduced the activated transcription factor NF-kB in the nuclei of RAW264.7 cells. The reduced levels of NF-kB p65 protein were correlated with those of iNOS and COX-2 protein expression.

DISCUSSION

Allergic diseases such as asthma, allergic rhinitis, atopic dermatitis, and food allergy afflict up to 20% of the human population in most countries. The etiology of allergy reactions is based on IgE-mediated pharmacologic processes in a variety of cell populations such as mast cells and basophils. Degradation of mast cells and basophils with anti-IgG Fab or anti-IgG F(ab')2 mediates antihistamine action during the present investigation using guinea pig ileum, as previously reported. However, ginsenosides Rg3, Rf, and Rh2 at a concentration of 0.2 mM inhibited almost no histamine action (data not shown), although Tachikawa et al. reported that ginsenoside Rg3 weakly inhibited histamine-induced ileum contractions in the guinea pig. These ginsenosides did not scavenge the superoxide anion, although some antiallergic and antipsoriatic agents are scavengers of active oxygen species. In the previous study, the membrane-stabilizing effects of ginsenoside Rh2 were greater than those of DSCG. These results suggest that the inhibitory action of these ginsenosides on the release of β-hexosaminidase may be due to protection of the degranulation response by antigen-IgE. These ginsenosides also showed the most potent inhibitory activity against the PCA reaction.

Contact dermatitis is accompanied by sustained swelling, predominant epidermal hyperplasia, and marked infiltration of inflammatory cells consisting of monocytes, granulocytes, and macrophages, but not eosinophils. In the present study, oxazolone-induced dermatitis was also accompanied by sustained swelling and predominant epidermal hyperplasia as reported by Fujii et al. IFN-γ and TNF-α, which are cytokines involved in chronic inflammatory skin disease, and COX-2, which is an acute marker of acute inflammatory disease, were induced. COX-2, an inducible isozyme of COX, is upregulated in skin inflammation and carcinogenesis. Hernandez et al. reproted that COX-2 was induced in angiogenesis-related diseases such as rheumatoid arthritis and psoriasis. The ginsenosides Rf, Rg3, and Rh2 significantly inhibited sustained swelling (thickness) of mice ears induced by oxazolone as well as mRNA levels of COX-2. Furthermore, these ginsenosides significantly inhibited mRNA levels of TNF-α and IL-1β produced by macrophages. In the previous study, these ginsenosides inhibited NO and prostaglandin E2 biosynthesis in LPS-induced RAW264.7 cells. However, these ginsenosides did not inhibit the activities of COX-1 and -2. These findings support the hypothesis that these ginsenosides inhibit the expression levels of iNOS and COX-2 proteins in RAW264.7 cells induced by LPS. KRGs and ginsenosides potently inhibited the increase in oxazolone-induced IFN-γ mRNA level but weakly inhibited the increase in IL-4 mRNA level produced by Th2 cells. These results suggest that these ginsenosides can improve chronic and inflammatory skin disorders, contact dermatitis, or psoriasis by the regulation of COX-2, TNF-α, and IL-1β produced by macrophages and IFN-γ and IL-4 produced by Th cells. We therefore believe that KRGs and its genuine ginsenosides Rg3, Rf, and Rh2 have extensive antiallergic and anticontact dermatitis activities.
