Through screening for natural ligands against peroxisome proliferator-activated receptor γ (PPARγ) using the PPARγ luciferase reporter assay, 6 hydroxy unsaturated fatty acids were isolated from adlay seed (Coix lacryma-jobi L. var. ma-yuen STAFF.) extracts with acetone and 70% ethanol. The structures of these compounds were determined via spectral analysis as 13-hydroxy-(9E,11E)-octadecadienoic acid (13-E,E-HODE) (1), 9-hydroxy-(10E,12E)-octadecadienoic acid (9-E,E-HODE) (2), 9-hydroxy-(10E)-octadecenoic acid (3), 10-hydroxy-(8E)-octadecenoic acid (4), 8-hydroxy-(9E)-octadecenoic acid (5), 11-hydroxy-(9Z)-octadecenoic acid (6), 9-E,E-HODE (2) exhibited the most potent PPARγ agonist activity of the isolated hydroxy unsaturated fatty acids. 9-E,E-HODE (2) and 13-E,E-HODE (1) are the respective geometrical isomers of 9-hydroxy-(10E,12Z)-octadecadienoic acid and 13-hydroxy-(9Z,11E)-octadecadienoic acid, both of which are likely to be natural PPARγ agonists produced in various mammalian cells, suggesting that 9-E,E-HODE may also act as PPARγ agonist.

Key words Adlay seed; peroxisome proliferator-activated receptor γ; fatty acid; 9-hydroxyoctadecenoic acid; 13-hydroxy-octadecadienoic acid

Peroxisome proliferator-activated receptor γ (PPARγ) is a master regulator in adipogenesis, implicated in whole-body glucose homeostasis and insulin sensitivity, and is the molecular target of thiazolidinediones, which sensitize cells to insulin and have antidiabetic effects in the liver, adipose tissue and skeletal muscle.¹,² Recent studies have revealed that PPARγ is expressed in various tissues or cells involved in the control of various physiological responses including inflammation, bone homeostasis, and blood pressure.³,⁴ PPARγ not only activates transcription of target genes for lipid metabolism, but also transrepresses expression of genes for the inflammatory response.⁵ Suppression of the inflammatory response by PPARγ agonists is closely linked to anti-diabetic and anti-atherosclerotic effects. Thus, new insights into the pleiotropic roles of PPARγ on cellular functions may lead to the development of effective treatment using PPARγ agonists against various inflammatory disorders including diabetes, atherosclerosis, rheumatoid arthritis and bowel disease. Presently thiazolidinediones have high efficacy but a number of deleterious side effects such as peripheral edema, fluid retention and significant weight gain.⁶ These adverse effects, particularly edema and fluid retention, are especially severe for patients with pre-existing cardiovascular disease due to the increased incidence of chronic heart failure from fluid accumulation and edema.⁷ To prevent the adverse effects of PPARγ full agonists, novel PPARγ agonists that retain beneficial clinical effects without side effects are being investigated through specific PPAR modulation in a tissue- or cell-selective manner.

The adlay seed (Coix lacryma-jobi L. var. ma-yuen STAFF.), an herbal crude drug, has been widely used in Asian countries for the treatment of rheumatism, warts, neuralgia, and female endocrine disorder from ancient times. Recent studies have demonstrated that the adlay seed exhibits anti-inflammatory, anti-obesity, anti-hyperlipidemia, anti-tumor, anti-allergic, and anti-microbial effects.⁸—¹² Some active compounds previously isolated from the adlay seed include coixenolides that possess anti-tumor effects,¹³ coixans A, B, and C that possess hypoglycemic effects,¹⁴ and benzoazinones that possess anti-inflammatory effects.¹⁵ In our search for novel PPARγ agonists, we selected 88 herbal crude drugs that are frequently used in Kampo medicines. Compounds isolated from the adlay seed extract showed relatively high PPARγ agonist activity and the structures of the active compounds were determined to be hydroxy unsaturated fatty acids. Here, we report the activity and structure of these active compounds isolated from the adlay seed.

MATERIALS AND METHODS

General Experiment Procedures The NMR spectra were recorded in CD₃OD using either a JEOL, Lambda-500 or ECA-500 spectrometer. ¹H- and ¹³C-NMR chemical shifts were referenced to the central peak of CD₃OD. Electron impact mass spectra (EI-MS) were measured with a JEOL SX-102 spectrometer. Silica gel BW-200 (Fuji Silysia Chemicals Co., Ltd.) was used for column chromatography. Chromatographic fractions were monitored by TLC using pre-coated plates (Kieselgel 60 F254, 0.25 mm thick, Merck no. 5715) and then detected by UV light at 254 nm and by color reaction following heating the plates after spraying with a solution of vanillin in sulfuric acid/ethanol. Adlay seed and other crude drugs were purchased from Tsumura & Co. (Tokyo, Japan). HEK293 and 3T3-L1 cells were obtained from the RIKEN Cell Bank (Tsukuba, Japan) and JCRB Cell Bank (Osaka, Japan), respectively.

Extraction and Isolation Dry adlay seeds (2.0 kg) were extracted with 100% acetone (141×3 times) at room temperature for 24 h. The extracts were filtered, combined and concentrated in vacuo. The residue (103 g) was suspended in
80% MeOH and partitioned with n-hexane to obtain n-hexane-soluble material (98.7 g). The 80% MeOH soluble material was then suspended in H2O and further partitioned with AcOEt to obtain AcOEt-soluble (2.15 g) and H2O-soluble (2.62 g) material. Among these 3 fractions, the AcOEt soluble material showed the highest PPARγ transcriptional activity. Therefore, the AcOEt fraction was subjected to silica gel column chromatography (n-hexane : AcOEt=3:2) to obtain 7 fractions. The most potent fraction was further separated on silica gel column chromatography (chloroform : AcOEt=9:1) into 3 fractions. The active fraction was subjected to preparative reverse-phase high-performance liquid chromatography (HPLC) (YMC J’shere ODS-H80, 10 mm×250 mm; 70% acetonitrile) to yield the following hydroxy unsaturated fatty acids as active compounds: 5 (3.4 mg), 6 (11.9 mg); compounds 5 and 6 together with 1–4 made up the active compounds of the adlay seeds.

- **11**: 1.50 (2H, m, 4–7, 14–17-H2), 1.58 (2H, m, 3-H2), 2.07 (2H, m, J=6.9, 6.9 Hz, 8-H), 2.26 (2H, m, 2-H2), 4.00 (1H, dt, J=6.9, 6.3 Hz, 9-H), 5.50 (1H, dd, J=14.9, 6.9 Hz, 10-H), 5.66 (1H, dt, J=15.2, 6.8 Hz, 13-H), 6.01 (1H, dd, J=14.9, 10.3 Hz, 12-H), 6.12 (1H, dd, J=15.2, 10.3 Hz, 11-H).

**Luciferase Reporter Assay**

PPARγ agonist activity was determined by luciferase reporter assay as follows. HEK293 cells (1.5×10⁶ cells/well) were seeded in 24-well culture plates and maintained in minimal essential medium (MEM) containing 10% fetal bovine serum (FBS) and 10 ml/l of non-essential amino acid at 37 °C under 5% CO2 in air. The cells were transfected by a standard calcium-phosphate precipitation method with 100 ng pCMX-PPARγ1 expression vector, 100 ng pPRES-3-K luciferase plasmid and 10 ng pCMX-β-gal expression vector. After incubating for 20 h, the cells were thoroughly washed with fresh medium and continued to incubate in the presence of the compounds at the concentrations indicated in the figure legends. After incubating for an additional 20 h, the cells were harvested to determine the luciferase and β-galactosidase activity. Luciferase activity was normalized relative to the activity of an internal β-galactosidase control and expressed as the relative luciferase activity. The luciferase activity was determined in triplicate experiments.

**Binding Activity of PPARγ Agonist**

A binding assay was performed using Nu ligand kit (Microsystems, Kyoto, Japan) according to the manufacturer’s instructions. Briefly, 100 μl glutamine S-transferase-fused nuclear receptor protein dissolved in 0.1 m sodium carbonate buffer (pH 6.8) was added to a 96-well plate and incubated overnight at 4°C. After washing the plate thoroughly with fresh medium and continued to incubate in the presence of the compounds at the concentrations indicated in the figure legends. After incubating for an additional 20 h, the cells were harvested to determine the luciferase and β-galactosidase. Luciferase activity was normalized relative to the activity of an internal β-galactosidase control and expressed as the relative luciferase activity. The luciferase activity was determined in triplicate experiments.
with DMEM supplemented with 10% CS, 1 μg/ml insulin, 0.25 μM dexamethasone, 0.5 mM 3-isobutyl-1-methylxanthine (IBMX), 100 U/ml penicillin, and 100 μg/ml streptomycin and cultured for 2 d. Then, the medium was replaced with DMEM supplemented with 10% CS, 0.5 μg/ml insulin, 100 U/ml penicillin, and 100 μg/ml streptomycin and cultured for an additional 2 d. Finally, the cells were maintained in DMEM containing 10% CS, 100 U/ml penicillin, and 100 μg/ml streptomycin, while the medium was replaced with fresh media every 2 days. On day 8, the cells were washed twice with cold phosphate-buffered saline (PBS), fixed in 10% formaldehyde in PBS for 1 h and then stained with 0.3% (w/v) Oil red O solution (60% isopropanol, 40% water) for 1 h at room temperature. After staining, the cells were washed three times with water and then photographed.

**Statistical Analysis**

Data were expressed as the means±S.D. Data were evaluated for statistical significance by one-way ANOVA, followed by Bonferroni’s t-test or by Student’s t-test. A value of p<0.05 was considered to be statistically significant.

**RESULTS**

A total of 88 herbal crude drugs frequently used in Kampo medicines were selected and screened for PPARγ agonist activity by the PPARγ luciferase reporter assay. The adlay seed showed a higher PPARγ transcriptional activity than the other herbal crude drugs (PPARγ agonist troglitazone (5 μM): 3.36±0.40, adlay seed: 1.95±0.15, artemisia capillaris flower: 1.78±0.34, chrysanthemum flower: 1.70±0.12, trichosanthes seed: 1.54±0.11, anemarrhena rhizoma: 1.47±0.15, glycyrhiza: 1.42±0.23, schizonepeta spike: 1.41±0.19 (crude drug extracts were used at the concentration of 50 μg/ml)). To isolate the active compounds, both the acetone and 70% EtOH extracts of adlay seeds were fractionated following the PPARγ reporter assay using various methods of chromatography to yield the final hydroxy unsaturated fatty acids 1—4 from acetone extraction and 5 and 6 from 70% EtOH extraction (Fig. 1).

The EI-MS results of 1 showed a dehydrated fragment ion peak at m/z 278. The UV (λmax: 235 nm) and 1H-NMR spectra indicated that 1 possesses conjugated olefins. The J values (14.9, 15.1 Hz) of olefin protons and the COSY spectrum also indicated that 1 possesses a conjugated E,E-diene with a hydroxy group at the allyl position in the straight carbon chain. To determine the position of the hydroxy group and the olefins, trimethylsilylation of 1 was performed, followed by EI-MS measurement. As the EI-MS results showed the fragment ion peak for TMS ether at 271 ([M+TMS]+), Fig. 2), the position of the hydroxy group was determined to be 13-hydroxy-(9E,11E)-octadecadienoic acid (13E-ET-ODE).

Compound 2 showed very similar spectral data to 13-E,E-ODE (1), suggesting it also was a hydroxy-(E,E)-octadecadienoic acid. The EI-MS results of TMS ether showed a fragment ion peak at 225 ([M−C7H13O2]+), indicating the position of the hydroxy group of 2 was at C-9. The positions of the hydroxy group and olefins of 2 were also supported by the correlation between terminal methyl (δ 0.89) and 14-H2 (δ 2.06) in the HOHAHA spectrum (Fig. 1). Thus, the structure of 2 was determined to be 9-hydroxy-(10E,12E)-octadecadienoic acid (9-E,E-ODE).

The EI-MS results of 3 showed a dehydrated peak at m/z 280, which was 2 mass units larger than that of 13-E,E-ODE (1). The 1H-NMR results of 3 showed similar spectral data to 13-E,E-ODE (1), except for that corresponding to one E olefin. The EI-MS results of 3 showed a fragment ion peak for TMS ether at m/z 227 ([M−C7H13O2]3, Fig. 2). Taken together, the structure of 3 was determined to be 9-hydroxy-(10E)-octadecadienoic acid.

The spectral data of 4 and 5 were very similar to those of 3, indicating that they are isomers of 3. As the EI-MS results of 4 and 5 showed the fragment ion peaks for TMS ethers at 257 ([M−C7H13]+) and 241 ([M−C7H13]+), respectively, the structure of 4 was determined to be 10-hydroxy-(8E)-octadecenoic acid and 5 to be 8-hydroxy-(9E)-octadecenoic acid.

Compound 6 also had similar spectral data to those of 3, except for those corresponding to the olefins. As the J values of olefin protons were 11.0 Hz and the EI-MS results of 6 showed the fragment ion peak for TMS ether at 271 ([M−C7H13]+), Fig. 2), the structure of 6 was determined to be 11-hydroxy-(9Z)-octadecenoic acid. As the optical rota-
Cell differentiation in a similar manner to the PPAR

Fig. 3. Effects of Hydroxy Unsaturated Fatty Acids Isolated from Adlay Seeds on Activation of PPARγ in Luciferase Reporter Assay

ppPREx3-TK-luc and pCMX-βGal were transfected into HEK293 cells together with pCMX-PPARγ1. 20 h after the transfection, the cells were treated with various hydroxy unsaturated fatty acid 1—6 at the concentration of 2 μM (open column) or 20 μM (hatched column) for 20 h. The activity of vehicle control set at 1, and relative luciferase activity was presented as fold induction relative to that of the vehicle control. Troglitazone (TGZ) (5 μM) was used as a PPARγ agonist. The values are represented as means±S.D. of three determinants from a representative of three independent experiments, which showed similar results. ∗p<0.05, ∗∗p<0.01 vs. vehicle control (Student’s t-test).

Fig. 4. Relative Activation of PPARγ and Binding Activity to PPARγ by 9-E,E-HODE (2)

(A) ppPREx3-TK-luc and pCMX-βGal were transfected into HEK293 cells together with pCMX-PPARγ1. 20 h after the transfection, the cells were treated with EPA, eicosapentaenoic acid, LA; linoleic acid, OA; oleic acid, SA; stearic acid, 13-HODE, 9-HODE, 13-E,E-HODE (13-HODE), which are geometrical isomers of 9-E,E-HODE (2) and 13-E,E-HODE (1), respectively, are reported to be physiologically relevant endogenous PPARγ agonists in mammals. Polysaturated fatty acids are also known to be endogenous PPARγ agonists. As in similar reports, 9-HODE showed the most potent activity, followed by 13-HODE, eicosapentaenoic acid and linoleic acid (Fig. 4A). On the other hand, 9-E,E-HODE (2) showed a PPARγ agonist activity as potent as 9-HODE and much more potent than eicosapentaenoic acid and linoleic acid (Fig. 4A), and 13-E,E-HODE (1) was a less potent PPARγ agonist than 13-HODE but comparable to eicosapentaenoic acid and linoleic acid.

Investigation of the binding activity of 9-E,E-HODE (2) and 13-E,E-HODE (1) to PPARγ by determining agonist-dependent interaction of PPARγ with a coactivator TIF2 using the CoA-BAP assay system revealed that both 9-E,E-HODE (2) and 13-E,E-HODE (1) bound directly to PPARγ to the same degree that troglitazone did (Fig. 4B). To study the PPARγ agonist activity of 9-E,E-HODE (2) in cells, the effect on differentiation of 3T3-L1 preadipocyte cells to adipocytes was also examined. As shown in Fig. 5, 9-E,E-HODE (2) was confirmed to induce 3T3-L1 preadipocyte cell differentiation in a similar manner to the PPARγ full agonist rosiglitazone and 9-HODE; a similar effect was also observed in the adlay seed extract. Finally, as 9-HODE and 13-HODE are reported to activate PPARα, we studied whether 9-E,E-HODE (2) and 13-E,E-HODE (1) are able to activate PPARα in PPARα luciferase reporter assay. Although data are not shown, the results indicate that both 9-E,E-HODE (2) and 13-E,E-HODE (1) activate PPARα-de-
vated by 15-deoxy-\(\Delta^{12,14}\)-PGJ\(_2\), 9-HODE, 13-HODE, 5-, 12-, and 15-hydroxyeicosatetraenoic acids (15-HETE) as endogenous agonists, although the physiological relevance of the agonists has not been determined.\(^{27}\) However, Itoh et al. recently reported that PPAR\(\gamma\) can accommodate two 9-HODE molecules simultaneously or one 13-HODE molecule at a different position in the large ligand-binding pocket of PPAR\(\gamma\).\(^{16}\) These results strongly suggest that 9-HODE and 13-HODE, in addition to o xo fatty acids, are physiologically relevant PPAR\(\gamma\) agonists. In our study, 9-E,E-HODE (2) was found to activate PPAR\(\gamma\)-dependent transcriptional activity as efficiently as 9-HODE in the PPAR\(\gamma\) luciferase reporter assay and it induced the differentiation of 3T3-L1 preadipocyte cells to adipocytes, whereas 13-E,E-HODE (1) showed less potent PPAR\(\gamma\) agonist activity than 13-HODE. PPAR\(\gamma\) has a large Y-shape ligand-binding pocket with a volume of around 1400 \(\AA^3\) and can accommodate one or a couple of various lipophilic ligands. According to Itoh et al., the binding of two 9-HODE molecules or one 13-HODE molecule stabilizes the conformation of PPAR\(\gamma\), resulting in transmitting signals, suggesting that 9-E,E-HODE (2) may also be accommodated to the same position in the ligand-binding pocket, regardless of the conformational difference of 9-E,E-HODE (2) with two \textit{trans} double bonds. On the other hand, the difference in the structure of 13-E,E-HODE (1) and 13-HODE may affect the entry and/or binding of 13-E,E-HODE (1) to the PPAR\(\gamma\)-binding pocket, or the 13-E,E-HODE (1)-induced PPAR\(\gamma\) conformational change may fail to recruit coactivators or release corepressors, resulting in a significant reduction in the activation of PPAR\(\gamma\)-dependent gene transcription. Therefore, assuming a difference exists in the binding ability between 9-E,E-HODE (2) and 9-HODE, 9-E,E-HODE (2) may induce a subtle conformational change in PPAR\(\gamma\), resulting in the recruitment of different coactivators and the activation of a set of genes distinct from 9-HODE. This notion is supported by the fact that 13-HODE and 15-HETE, as well as rosiglitazone, preferentially induce the interaction of PPAR\(\gamma\)/retinoid X receptor (RXR) heterodimers with a coactivator cyclic AMP response element binding protein (CREB)-binding protein, whereas 15-deoxy-\(\Delta^{12,14}\)-PGJ\(_2\) induces the interaction with steroid receptor coactivator-1.\(^{25}\) Taken together, our major findings show that 9-E,E-HODE (2) is as potent a PPAR\(\gamma\) agonist as 9-HODE, despite being a geometrical isomer, and is more potent than other polysaturated fatty acids; and demonstrate that the adlay seed is rich in exogenous PPAR\(\gamma\) agonists similar to physiologically relevant endogenous PPAR\(\gamma\) agonists.

Although there are few studies concerning PPAR\(\gamma\)-dependent effects of 9-HODE and 13-HODE, a recent study has demonstrated that 13-HODE can be produced from linoleic acid by 12/15-lipoxygenase that is induced in macrophages by interleukin (IL)-4, inhibiting the transcriptional activity of nuclear factor of activated T cells (NFAT) and nuclear factor-\(\kappa\)B (NF-\(\kappa\)B) in phorbol myristate acetate-activated peripheral blood T cells, resulting in the suppression of IL-2 production.\(^{29,30}\) Given that 9-HODE can be produced in monocytes or lymphocytes,\(^{20}\) leading to activation of PPAR\(\gamma\) that is more potent than 13-HODE activation,\(^{18}\) 9-HODE is expected to exhibit anti-inflammatory or immunomodulating activity more efficiently than 13-HODE. Therefore, 9-E,E-HODE (2), as a potent PPAR\(\gamma\) agonist, may also serve as an inflammatory modulator like 9-HODE. Presently, the synthetic PPAR\(\gamma\) agonists thiazolidinediones are widely used as insulin sensitizers, and other anti-inflammatory drugs that can activate PPAR\(\gamma\) are used in the treatment of inflammatory bowel diseases.\(^{31}\) In addition to the present PPAR\(\gamma\) agonists, 9-E,E-HODE (2) may also be a potential therapeutic agent for insulin resistance, diabetes, and bowel diseases. Moreover, the adlay seed has been reported to exhibit anti-inflammatory, anti-obesity, anti-hyperlipidemia, and anti-allergic effects, some of which may be explained by the effects of 9-E,E-HODE (2) and other hydroxy unsaturated fatty acids. To date, some PPAR\(\gamma\) agonists have been isolated from plants and their active compounds included coumarin,\(^{32}\)
prenylflavonoids,\textsuperscript{33} and triterpenoids,\textsuperscript{34–36} the structures of which are much different from those of hydroxy unsaturated fatty acids. Although only a few PPAR\(\gamma\) agonists have been isolated for the first time from adlay seeds in the present study, additional PPAR\(\gamma\) agonists with other distinct structures need to be determined to further understand the complexity of PPAR\(\gamma\) regulation and development of potential PPAR\(\gamma\) agonists.

In summary, 6 hydroxy unsaturated fatty acids were isolated and their structures determined. Among them, 9-E,9-HODE (2), a geometrical isomer of 9-HODE, exhibited PPAR\(\gamma\) agonist activity as potent as 9-HODE. The finding that 9-E,9-HODE (2), which seems to possess characteristics distinct from 9-HODE, exists in adlay seeds may support the clinical usage of adlay seeds as a therapeutic agent for inflammatory diseases, diabetes, or insulin resistance and the development of novel PPAR\(\gamma\) agonists without a number of deleterious effects such as peripheral edema, fluid retention and significant weight gain, shown by thiazolidinediones.\textsuperscript{63} Future studies need to focus on the biosynthetic pathway of 9-E,9-HODE (2) in adlay seeds.
