Thymosin β4, a major G-actin-sequestering protein, is known to be involved in tumor metastasis. In the present study, we found that thymosin β4 expression promotes the formation of actin-based pseudopodia-like extensions, associated with cell migration, in human prostate cancer LNCaP cells. Treatment with the phosphatidylinositol 3-kinase (PI3K) inhibitor wortmannin and Cdc42/Rac1/RhoA inhibitor Clostridium difficile toxin B significantly reduced pseudopodia formation in thymosin β4-overexpressing LNCaP cells, suggesting that the pseudopodia formation by thymosin β4 is probably involved in PI3K and Rho family pathway. We recently reported that thymosin β4 expression is upregulated by androgen deprivation in prostate cancer cells. The increase in thymosin β4 may be one of the causes of prostate cancer progression after androgen ablation therapy.

Key words thymosin β4; LNCaP; pseudopodia; migration

Most patients with advanced prostate cancer are candidates for androgen ablation therapy because growth and progression of prostate cancer cells are initially androgen dependent.1,2) Although androgen ablation therapy initially causes tumor regression in >80% of cases, prostate cancer eventually progresses from an androgen-dependent to an aggressive androgen-independent state after the therapy, and the prostate cancer in this state is often difficult to cure.2,3) One of the reasons why prostate cancer cells after androgen ablation therapy acquire aggressive phenotype is changes in the expression of androgen-regulated genes after the therapy.4,5) In our recent study, we found that thymosin β4 expression in androgen-sensitive prostate cancer LNCaP cells is elevated in androgen-deprived culture condition.6)

Thymosin β4 is a small acidic 4.9-kDa polypeptide widely distributed in human tissues. Thymosin β4 functions as a major G-actin sequestering factor that modulates dynamic changes of actin cytoskeleton.7) In addition, thymosin β4 is involved in a variety of physiologic and pathologic processes. For example, thymosin β4 is known to promote wound healing, tumor metastasis, and angiogenesis.8,9-10) Overexpression of thymosin β4 is detected highly in metastatic cancer cells.11-13) GDNF-

MATERIALS AND METHODS

Materials Wortmannin was purchased from Sigma-Aldrich Japan K.K. (Tokyo, Japan). Toxin B from Clostridium difficile was from List Biological Laboratories (Campbell, CA, U.S.A.). U0126 was purchased from Wako Pure Chemical (Osaka, Japan). Rapamycin was from Merck Ltd. (Tokyo, Japan).

Cell Culture Human prostate cancer LNCaP cells were from American Type Culture Collection (Rockville, MD, U.S.A.). LNCaP cells were cultured in RPMI-1640 medium containing 10% fetal calf serum (FCS) under a humidified atmosphere with 5% CO₂ at 37 °C.

Plasmid Constructions Total RNA from LNCaP cells was extracted using TRizol reagent (Invitrogen, Carlsbad, CA, U.S.A.) then first-strand complementary DNA was synthesized from the total RNA using SuperScript III (Invitrogen) according to the manufacturer’s instructions. The cDNA coding region of human thymosin β4 was amplified by polymerase chain reaction (PCR) from the cDNA using primers containing restriction sites for XbaI and HindIII. The sequences of the primers were, sense: 5′-GCTCTAGAT-GTCTGACAAACCGATATG-3′; antisense: 5′-CCAGAGCTTTACGATTGCCTGCTTGTTC-3′. PCR was performed using PrimeSTAR HS DNA Polymerase (Takara Bio Inc., Otsu, Japan) under the following conditions: 32 cycles of 30 s at 98 °C, 30 s at 58 °C, and 30 s at 72 °C. The resulting PCR product was digested with XbaI and HindIII and inserted into the XbaI and HindIII sites of a pRK5 mammalian expression vector. The plasmid vector was purified with Qiagen Plasmid Midi Kit (Qiagen, Hilden, Germany). The entire sequence of the cloned gene was determined by CEQ2000XL (Beckman Coulter, Fullerton, CA, U.S.A.) then first-strand complementary DNA was synthesized from the total RNA using SuperScript III (Invitrogen) and subjected to PCR amplification with the following primers: thymosin β4 antisense, 5′-GCTGTTCAATCGT-3′; thymosin β4 sense, 5′-GCTGTTCAATCGT-3′; glyceraldehyde-3-phosphate dehy-

dreonase (GAPDH) sense, 5′-CCAGCAAGAGCACAAGGGAG-CA-3′; GAPDH antisense, 5′-GCAACTGTGAGGAGGGGAGA-3′. The optimal PCR conditions were determined as the amount of amplification product in proportion to that of input RNA. PCR was performed under the following conditions: 26 cycles of 30 s at 98 °C, 30 s at 58 °C, and 30 s at 72 °C for thymosin β4; 21 cycles of 30 s at 94 °C, 30 s at 60 °C, and 30 s at 72 °C for GAPDH. GAPDH served as internal RNA control to allow comparison of RNA levels among different specimens. After PCR, the reaction products were resolved on 1.5% agarose gels and visualized with ethidium bromide.

**Transwell Chamber Assay** In vitro invasion ability of the cells was assayed using a Transwell cell-culture chamber, as described previously with some modifications. Briefly, the upper surface of the membrane with an 8.0-μm pore size (Becton Dickinson, Franklin Lakes, NJ, U.S.A.) in a cell culture insert was coated with or without 20 μg Matrigel dissolved in 100 μl of phosphate buffered saline (PBS) and dried at room temperature. Cells suspended in 100 μl of DMEM containing 2% FCS were seeded at a density of 2.5 × 10⁴ cells/well into the cell culture insert and the insert was placed onto a well filled with the same medium containing 10% FCS in a 24-well culture plate (Nalge Nunc, Rochester, NY, U.S.A.) and incubated for 48 h in a CO₂ incubator. After incubation, the filters were fixed with 5% glutaraldehyde and stained with Giemsa’s solution (Merck, Darmstadt, Germany). The cells on the lower surface of the membrane of the chamber were counted. Percent invasion was calculated by the number of cells invaded through Matrigel-coated membrane divided by the number of cells migrated through control without Matrigel membrane, multiplied by 100.

**In Vitro Scratch Wound Migration Assay** LNCaP cells (6 × 10⁵ cells) were seeded into 35-mm dishes in DMEM containing 10% FCS without antibiotics. After 24 h, the cells were transfected with 2 μg of empty vector or thymosin β4 expression vector. The cells were further incubated for 24 h then wounded with a pipet tip. Photographs were taken with a microscope at 0, 12, 24, 48, and 72 h after wounding, and the width of the wound was measured. Migration ratio (%) was calculated by the width at each hour divided by the width at 0 h, multiplied by 100. In the case of the study of effect of various inhibitors on the formation of pseudopodia, cells were pretreated with an inhibitor for 24 h (wortmannin, rapamycin, U0126) or 1 h (C. difficile toxin B) and then wounded. Photographs were taken with a microscope at 4 h after wounding and the number of pseudopodia was counted.

**Phalloidin-Staining of F-Actin** Twenty-four hours after transfection, the cells were seeded on coverslips at a density of 3 × 10⁴ cells/coverslip and incubated for 24 h. After washing with PBS, the cells were fixed in 2% paraformaldehyde for 20 min. The fixed cells were made permeable by treatment with 0.1% Triton X-100 at room temperature for 5 min. The cells were washed thrice with PBS and stained with 0.4 μM Phalloidin-Fluorescein isothiocyanate (Sigma-Aldrich Japan K.K., Tokyo, Japan) for 40 min. After washing thrice with PBS, images were obtained by confocal laser scanning microscopy (LSM510, Carl Zeiss, Jena, Germany).

**Statistical Analysis** Data presented are the mean ± S.D. values from at least two individual experiments, and each experiment was performed in triplicate. Statistical significance of differences among the groups was assessed by one-way analysis of variance followed by Dunnet’s test. p-values < 0.05 were considered statistically significant.

**RESULTS**

**Increased Migration and Invasion of LNCaP Cells Transfected with Thymosin β4** We first examined the expression level of thymosin β4 in LNCaP cells transfected with the thymosin β4 expression vector or empty vector. RT-PCR analysis showed that thymosin β4 expression was significantly higher in the cells transfected with thymosin β4 expression vector as compared with those transfected with empty vector (Fig. 1A).

To study the effect of increased thymosin β4 expression on cell invasion and migration, we performed transwell chamber assay and in vitro scratch wound migration assay. As can be seen in Fig. 1B, invasion of cells transfected with thymosin β4 expression vector was about 2.3-fold higher than that of those transfected with empty vector. The migration of cells transfected with thymosin β4 expression vector was also apparently higher at all time points compared with that of those transfected with empty vector (Fig. 1D). Representative images of migration assay at 48 h after transfection are shown in Fig. 1C. The growth rate of thymosin β4-transfected cells was not significantly changed (about 1.1 times) compared with that of empty vector-transfected cells as estimated by alamar blue assay, implying that the increased wound healing of these cells is due to their migration increase.

**Increased Pseudopodia Formation in Thymosin β4-Transfected LNCaP Cells** We found that pseudopodia-like extensions were formed in cells transfected with thymosin β4 expression vector, especially at 4 h after wound, while those in the control cells were smaller and less numerous (Fig. 2A). The pseudopodia extension in thymosin β4 overexpressing-LNCaP cells exhibited a filopodia-like morphology. In addition, LNCaP cells overexpressing thymosin β4 tended to have elongated actin-based tails (Fig. 2B). We then examined the effect of various inhibitors on the formation in thymosin β4-transfected LNCaP cells to investigate the mechanism. Figure 3 shows that wortmannin (PI3K inhibitor) and C. difficile toxin B (Cdc42/Rac1/RhoA inhibitor) but not rapamycin (mTOR inhibitor) and U0126 (Erk inhibitor) significantly decreased the number of pseudopodia. Dead cells were not observed after treatment with wortmannin or toxin B, suggesting that the effects were not due to non-specific toxicity to LNCaP cells. Cdc42/Rac1/RhoA inhibitor C. difficile toxin B also blocked pseudopodia formation.

**DISCUSSION**

In this study, we found that thymosin β4 overexpressing LNCaP cells increase the formation of actin-based pseudopodia and cell migration. Pseudopodia (filopodia and lamellipodia) determine the direction of cell migration and produce the driving force for cell migration. Therefore induction of pseudopodia formation by thymosin β4 seems to be involved in the increase of cell migration.

What is the mechanism by which thymosin β4 causes
pseudopodia extension? Thymosin β4 activates various signaling pathways including integrin-linked kinase (ILK), Jnk-1, extracellular signal-regulated kinase (Erk), and c-Jun.14,16) In our study, pseudopodia formation was significantly inhibited by a PI3K inhibitor in thymosin β4 overexpressing LNCaP cells. ILK activity is positively regulated by PI3K, which leads to Cdc42 and Rac activation, then pseudopodia formation. In addition, the Rho family inhibitor predictably suppressed pseudopodia formation by thymosin β4 overexpression. These observations suggest that one possible explanation for the pseudopodia formation is activation of PI3K signaling pathway by thymosin β4.

Thymosin β4 is known to be released from cells.17,18) It is not clear whether the pseudopodia induction in thymosin β4 overexpressing LNCaP cells was mediated intracellularly and/or extracellularly. We have a preliminary result showing that cells with pseudopodia are different from those transfected with thymosin β4 expression vector, estimated by co-transfection with a plasmid expressing enhanced green fluorescent protein (pEGFP-N1) (data not shown). This suggests that the effect of thymosin β4 on pseudopodium formation may be cell non-autonomous.

There are several studies that demonstrate increased activity of cell invasion and migration by thymosin β4. For instance, thymosin β4 overexpressing mouse fibrosarcoma
cells have been reported to increase migration potential in vitro and tumorigenicity and metastatic potential in vivo. Overexpression of thymosin β4 in SW480 colon carcinoma cells has been shown to result in increased migration with enhanced focal adhesion. Moreover, thymosin β4 treatment has been revealed to increase motility of cardiac cells and endothelial cells, and the stimulated cell migration is caused by upregulation of ILK and Akt activities. In this study with LNCaP cells transfected with thymosin β4 expression vector, it was confirmed that invasion and migration abilities were increased by thymosin β4.

In summary, increased expression of thymosin β4 results in pseudopodia formation, associated with cell migration in prostate cancer LNCaP cells. We have recently reported that thymosin β4 expression is negatively regulated by androgen. The elevated thymosin β4 expression may be one possible cause for increased prostate tumor metastasis after androgen ablation therapy.
