Received July 15, 2009; accepted October 6, 2009

The present study was designed to clarify the effects of an ethanol extract of artichoke leaf on acute gastric mucosal injury in rats. Oral administration of artichoke leaf extract dose-dependently prevented absolute ethanol-induced (125—500 mg/kg) or restraint plus water immersion stress-induced gastric mucosal injury (1000—2000 mg/kg). The artichoke leaf extract contains 1% cynaropicrin and 0.8% chlorogenic acid as main components and 70% dextrin as a vehicle. Cynaropicrin at doses of 1/100 of artichoke leaf extract [ethanol-induced mucosal injury: 5 mg/kg, per os (p.o.); stress-induced mucosal injury: 20 mg/kg, p.o.] also prevented gastric mucosal injury in both animal models. However, dextrin and chlorogenic acid at doses contained in the leaf extract were ineffective in both models. When artichoke leaf extract was given orally to normal rats, it (500—2000 mg/kg, p.o.) dose-dependently increased gastric mucus content. In addition, it (125—500 mg/kg, p.o.) dose-dependently prevented the decrease in gastric mucus content by absolute ethanol. When the effects of artichoke leaf extract on basal gastric acid secretion in rats were evaluated, it (500—2000 mg/kg, p.o.) dose-dependently increased the volume of gastric juice in normal rats. However, it was ineffective in decreasing basal gastric acid secretion in normal rats. These results indicate that artichoke leaf extract is effective against acute gastritis and its beneficial effect is due to that of cynaropicrin. The gastric mucus-increasing action of artichoke leaf extract may be, at least in part, related to the anti-gastritic action of the extract.

Key words artichoke leaf extract; cynaropicrin; anti-gastritic action; gastric mucus

Artichoke (Cynara Scolymus L.) is a plant that is widely grown in Mediterranean countries, including southern France and California in the United States. It is rich in natural antioxidants. In general, the dried extract consisting of leaves and not flowering heads of artichoke has been eluted with water in European countries and the main components are caffeoylquinic acid derivatives (cynarin and chlorogenic acid), flavonoids (luteolin and apigenin) and bitters (cynaropicrin).1—4 Artichoke leaf extract has been used for hepatoprotective5,6 and cholesterol reducing7,8 purposes. Based on in vitro5,9,10 and in vivo6,11 studies, it is believed that artichoke leaf extract is very effective as an antioxidant and its beneficial effects are attributed to its antioxidant action. However, there is still no experimental evidence indicating which components possess the beneficial effects.

Artichoke leaf extract used in the present study was extracted by 45% ethanol and contains 1% cynaropicrin and 0.8% chlorogenic acid, 1.3% protein, 0.1% lipid, 3.0% ash, 21.3% carbohydrate and 2.5% water and 70% dextrin was added as a vehicle (Fig. 1A). Thus, cynaropicrin and chlorogenic acid are contained as the main components (Fig. 1B) and other components such as cynarin, luteolin and apigenin are not contained in this extract. Artichoke leaf extract is currently used in Germany and Switzerland as a remedy for indigestion.4 It is believed that bitter compounds such as cynaropicrin are responsible for the beneficial effects. It has been reported that cynaropicrin from Saussurea lappa has in vitro anti-inflammatory effects via its inhibition of the production of inflammatory mediators.12

Acute gastritis is produced by psychological or physical...
stress, alcohol and drugs such as steroidal or nonsteroidal anti-inflammatory drugs. The beneficial effects of artichoke leaf extract on acute gastritis have not yet been sufficiently examined in experimental studies. Therefore, in the present study, we investigated the effects of artichoke leaf extract containing cynaropicrin and chlorogenic acid on absolute ethanol- or restraint plus water immersion stress-induced acute hemorrhagic gastric mucosal injury in rats, and compared the effects to those of sofarcone, an anti-ulcer agent. Furthermore, in order to clarify the mechanisms of the gastric cytoprotective action of artichoke leaf extract, we examined the effects of artichoke leaf extract on gastric mucus content and basal gastric acid secretion in rats.

MATERIALS AND METHODS

**Animals** Male Sprague-Dawley strain SPF rats (Nippon SLC, Shizuoka, Japan) weighing 180—200 g, were used in the experiment. The animals were housed in an air-conditioned room at 23±1°C. All experimental procedures described were approved by the Experimental Animal Research Committee of Meijo University, Faculty of Pharmacy.

**Materials** The materials used were artichoke leaf extract and the components in the extract (dextrin, cynaropicrin and chlorogenic acid). Cynaropicrin and chlorogenic acid were mixed with dextrin [1% (wt/wt) cynaropicrin or 1% (wt/wt) chlorogenic acid +99% (wt/wt) dextrin. These materials were supplied by Ichimaru Pharco Co., Ltd. (Gifu, Japan) Sofalcone (Solan®) (Taisho Pharmaceutical Co., Ltd., Tokyo, Japan) and omeprazole (Fujisawa Astra, Osaka, Japan), anti-ulcer drugs, were used as comparative drugs.

**Measurement of Ethanolic-Induced Gastric Mucosal Injury** After the rats were fasted for 24 h, absolute ethanol was administered in a volume of 1 ml per 100 g of body weight into their stomachs. Each test material (artichoke leaf extract, dextrin, chlorogenic acid, cynaropicrin and sofarcone) was given orally in a volume of 1 ml per 100 g of body weight 2 h prior to ethanol administration. Distilled water as a control was given instead of test material. One hour after administration of a test material or distilled water, the animals were killed under ether anesthesia and the mucus content in gastric mucosa was determined by staining the mucus with 0.1% alcian blue according to the method of Kitagawa et al. In order to evaluate the effects of test materials on gastric mucosal injury and gastric mucus content after ethanol treatment, the rats were fasted for 24 h. Test material or distilled water was given orally 2 h before absolute ethanol treatment. One hour after ethanol treatment, the animals were killed under ether anesthesia and the degree of gastric mucosal injury was expressed as the mucosal lesion index (mm²) as described above. After the lesion index was measured, the mucus content in gastric mucosa was determined as mentioned above.

**Statistical Analyses** The results obtained are expressed as the mean±S.E.M. The data were analyzed by one-way analysis of variance, and the statistical significance among groups was determined by Tukey–Kramer’s multiple-range test. In all cases, p<0.05 was considered significant.

**RESULTS**

**Effects of Artichoke Leaf Extract, the Components and Sofalcone on Ethanol-Induced Gastric Mucosal Injury** Intragastric administration of absolute ethanol to control rats produced large hemorrhagic injury in the glandular stomach. Artichoke leaf extract at oral doses of 125, 250 and 500 mg/kg dose-dependently prevented the gastric mucosal injury by 43%, 95% and 99%, respectively (Fig. 2A). When the effects of the components contained in 500 mg/kg of artichoke leaf extract were evaluated, dextrin [495 mg/kg, per os (p.o.)] and chlorogenic acid (4 mg/kg, p.o.) given as a mixture of dextrin [396 mg/kg, p.o., 99% (wt/wt) of the mixture] were ineffective in preventing the mucosal injury (Fig. 2B). Cynaropicrin at an oral dose of 5 mg/kg given as a mixture with dextrin [495 mg/kg, p.o., 99% (wt/wt) of the mixture] markedly prevented the mucosal injury by 98% (Fig. 2B). Sofalcone, a comparative drug, at an oral dose of 100 mg/kg...
prevented the gastric mucosal injury by 50% (Fig. 2B). Thus, cynaropicrin at an oral dose of 1/100 of artichoke leaf extract showed a preventive effect equal to that of the extract. Representative photographs of the gastric mucosa are shown in Fig. 3.

Effects of Artichoke Leaf Extract, the Components and Sofalcone on Restraint Plus Water Immersion-Induced Gastric Mucosal Injury

The restraint plus water immersion stress loading to control rats for 4 h produced hemorrhagic injury in the glandular stomach. Artichoke leaf extract at oral doses of 1000, 1500 and 2000 mg/kg dose-dependently prevented the stress-induced gastric mucosal injury by 33% (not significantly), 84% and 99%, respectively (Fig. 4A). When the effects of the components containing in 2000 mg/kg of artichoke leaf extract were evaluated, dextrin (1980 mg/kg, p.o., 99% of the extract) and chlorogenic acid (16 mg/kg, p.o.) given as a mixture of dextrin (1584 mg/kg, p.o., 99% of the mixture) were ineffective in preventing the mucosal injury (Fig. 4A). Cynaropicrin at an oral dose of 20 mg/kg given as a mixture with dextrin (1980 mg/kg, p.o.) completely prevented the mucosal injury by 99% (Fig. 4B). On the other hand, sofalcone, at an oral dose of 200 mg/kg, prevented the gastric mucosal injury by 64% (Fig. 4B). Representative photographs of gastric mucosa are shown in Fig. 5.

Effects of Artichoke Leaf Extract, Cynaropicrin and Sofalcone on Gastric Mucus Content in Normal Rats

Artichoke leaf extract at oral doses of 500, 1000 and 2000 mg/kg increased gastric mucus content by 26% (not significantly), 51% and 79%, respectively, in a dose-dependent manner, compared to the control in normal rats (Fig. 6). However, the extract at oral doses of 125 and 250 mg/kg was ineffective in increasing the mucus content (data not shown). Cynaropicrin at an oral dose of 20 mg/kg given as a mixture with dextrin (1980 mg/kg, p.o.) markedly increased the mucus content by 135%, although at an oral dose of 5 mg/kg (+ dextrin 495 mg/kg, p.o.) it only showed a slight increase (50%). Sofalcone at an oral dose of 200 mg/kg significantly increased the mucus content by 66%, although at an oral dose of 100 mg/kg it did not show an obvious increase.

Effects of Artichoke Leaf Extract, Cynaropicrin and Sofalcone on Gastric Mucus Content after Intragastric
Administration of Ethanol

The preventive effects of artichoke extract and cynaropicrin given as a mixture with dextrin and sofalcone on absolute ethanol-induced gastric mucosal injury were almost equal to the results shown in Fig. 2 (data not shown). The gastric mucus content in absolute ethanol-treated control rats was 48% lower than that in the ethanol-untreated normal rats (Fig. 7). Artichoke leaf extract at oral doses of 125, 250 and 500 mg/kg dose-dependently...
increased the mucus content by 46%, 60% and 187%, respectively, compared to that of ethanol-treated control. Cynaropicrin at an oral dose of 5 mg/kg given as a mixture with dextrin (495 mg/kg, p.o.) and sofalcone at an oral dose of 100 mg/kg markedly increased the mucus content by 131% and 167%, respectively, compared to that of ethanol-treated control.

**Effects of Artichoke Leaf Extract, Cynaropicrin and Omeprazole on Basal Gastric Acid Secretion**

Artichoke leaf extract at oral doses of 500, 1000 and 2000 mg/kg dose-dependently increased the volume of gastric juice by 1.5- (not significantly), 2.5- and 2.9-fold, compared to the control (Fig. 8A). However, the extract at oral doses of 125 and 500 mg/kg did not affect the volumes of gastric juice (data not shown). Cynaropicrin at an oral dose of 20 mg/kg given as the mixture with dextrin (1980 mg/kg, p.o.) markedly increased the volume by 2.3-fold. However, artichoke leaf extract (500, 1000, 2000 mg/kg, p.o.) and cynaropicrin (20 mg/kg, p.o.) given as a mixture of dextrin (1980 mg/kg, p.o.) did not affect total acid output (Fig. 8B). Omeprazole (50 mg/kg, p.o.), a comparative drug, markedly decreased total acid output by 95% (Fig. 8B), although it showed no apparent effect on the volume of gastric juice (Fig. 8A).

**DISCUSSION**

The results of the present study indicate that artichoke leaf extract prevents ethanol-induced or restraint plus immersion stress-induced acute gastric mucosal injury in rats, at least in part, by its gastric mucus-increasing action. Furthermore, the results demonstrated that the anti-gastric action (gastric cytoprotective action) of artichoke leaf extract is mainly due to that of cynaropicrin, and not chlorogenic acid.

In the present experiments, artichoke leaf extract dose-dependently prevented ethanol-induced (125—500 mg/kg, p.o.) or stress-induced gastric mucosal injury (1000—2000 mg/kg, p.o.). In artichoke leaf extract eluted by 45% ethanol, cynaropicrin and chlorogenic acid are the main components. Of these two main components, cynaropicrin at an oral dose of 1/100 of artichoke extract (ethanol-induced injury: 5 mg/kg; stress-induced injury: 20 mg/kg) showed gastric cytoprotective actions equal to those of the extract in both experimental models. On the other hand, chlorogenic acid and dextrin, a vehicle, were ineffective in protecting gastric injuries in both animal models. In addition, other components (protein, lipid, ash or carbohydrate) were also ineffective (data not shown). Therefore, the present results indicate that the beneficial effects of artichoke extract on acute hemorrhagic gastritis are mainly due to that of cynaropicrin and not other components. It is worth noting that cynaropicrin at extremely small doses exhibited more beneficial effects than those of sofalcone.

It has been demonstrated that oxygen-derived free radicals are involved in the pathogenesis of ethanol-induced gastric mucosal injury.14,15) Ethanol-induced gastric mucosal injury has also been suggested to be due to impairments in defensive factors such as mucus16) and mucosal microcirculation17) in addition to free radicals. On the other hand, the major factors implicated in the development of stress-induced gastric mucosal injury include an increase in gastric acid secretion and a decrease in mucosal protection due to the reductions in mucus secretion, mucosal blood flow and prostaglandin biosynthesis.18) Therefore, in the next experiments, in order
to clarify the mechanisms of the gastric cytoprotective action of artichoke leaf extract, we examined the effects of artichoke leaf extract and cynaropicrin on the content of gastric mucus in rats, before and after ethanol treatment as a defensive factor against gastric mucosa. In addition, we examined the effects of both test samples on basal gastric acid secretion as an aggressive factor against gastric mucosa. In connection with mucus glycoprotein synthesis, the synthesis and secretion of glycoprotein in the presence of 2000 mg/kg, absolute ethanol-induced gastric mucosal injury via dilution of the ethanol concentration in the stomach by increasing the volume of gastric juice. In the present preliminary experiment, gastric juice was not detected at all in the stomach of any animals 2 h after oral administration of higher doses of artichoke extract, although a small volume of gastric juice was observed at 1 h. Therefore, in order to evaluate the effects of artichoke leaf extract and other test materials on ethanol-induced gastric mucosal injury, we administered test materials orally 2 h prior to the intragastric instillation of ethanol.

In the present study, we first demonstrated that artichoke leaf extract prevents both acute gastric mucosal injuries in rats via its gastric mucus-increasing action.

In summary, the results of the present study indicate that artichoke leaf extract has beneficial effects on acute hemorrhagic gastritis, at least in part, by its gastric mucus glycoprotein-increasing action. Further studies are needed to clarify whether or not the mucus-increasing action of artichoke extract is mediated by endogenous PGs or not.
