Renal ischemia-reperfusion (I/R) injury is a major cause of acute kidney injury via inflammation and cell apoptosis. Volatile anesthetics have been shown to exert organ-protective effects against kidney damage in vivo and in vitro. In the present study, we investigated the effects of isoflurane, a commonly used volatile anesthetic, on renal I/R injury and the underlying mechanisms. Rats subjected to renal I/R displayed higher serum creatinine and blood urea nitrogen levels than sham rats as well as severe histopathological damage. Renal I/R also resulted in a nuclear factor-κB (NF-κB)-mediated inflammatory response and dysfunction of the p53-Bax-caspase-3 apoptotic pathway. Rats preconditioned with 1.5% isoflurane for 2 h had better renal function and less tubular apoptosis 24 h after I/R injury than control rats. Pretreatment with isoflurane suppressed renal NF-κB activation, leading to a reduction in proinflammatory molecules (high-mobility group box 1, interleukin-1β, and tumor necrosis factor-α) both in the kidneys and circulation. In addition, rats subjected to isoflurane preconditioning had a higher Bcl-2/Bax ratio and less cleaved caspase-3. Our findings suggest that preconditioning with a clinically relevant concentration of isoflurane attenuates renal I/R injury, based at least in part on its ability to modulate renal inflammation and apoptosis.

Key words acute kidney injury; ischemia-reperfusion; volatile anesthetic; inflammation; apoptosis

MATERIALS AND METHODS

Animals and Experimental Groups Male Sprague Dawley rats (Department of Laboratory Animal Science, Peking University Health Science Centre, Beijing, China) weighing 300–350 g were used in this study. Animals were bred and maintained under standardized housing conditions with food and water ad libitum. All experiments were conducted in accordance with protocols approved by the Peking University Biomedical Ethics Committee Experimental Animal Ethics Branch (Beijing, China). Twenty-four rats were randomly divided into three groups with eight animals in each group using the random table method. The groups were defined as sham-operated control (Sham), renal I/R (I/R), and isoflurane preconditioning before renal I/R (ISO+I/R).

Isoflurane Preconditioning Isoflurane preconditioning was performed according to our previous studies. In brief, rats were placed in a temperature-controlled, transparent anesthetic chamber with inflow and outflow hoses. Isoflurane (Baxter Healthcare, Deerfield, IL, U.S.A.) was delivered in 100% oxygen at 2 L/min using agent specific vaporizers. Standard soda lime was placed at the bottom of the con-
tainer to clear the carbon dioxide. Gas composition including isoflurane, oxygen, and carbon dioxide within the anesthetic chamber was continuously analyzed with a gas monitor (Datex-Ohmeda, Louisville, CO, U.S.A.) by sampling gas at the outflow hose. Rats in the ISO+I/R group received 1.5% isoflurane for 2h followed by 30 min of wash-out before I/R. Rats in the sham and I/R groups received only 100% oxygen for 2h. This dosing protocol of isoflurane has been shown to not only have no cardiorespiratory compromise, but also effectively ameliorate renal I/R injury in mice. All rats breathed spontaneously in the chamber.

**Renal I/R Injury** The acute renal I/R injury model was created as described previously. Briefly, rats were anesthetized with an intraperitoneal injection of 30 mg/kg pentobarbital sodium. After intradural injections of 0.25% bupivacaine, a midline laparotomy was performed. Then the right kidney was removed, and the left kidney pedicle was shut by an artery clamp for 30min. After 30 min of left renal ischemia, occlusion clips were removed, and the incision was closed in two layers. The same procedure was performed in the sham group without the unilateral clamping process.

**Assessment of Renal Function** Serum creatinine (Scr) and blood urea nitrogen (BUN) levels were measured using an automatic biochemical analyzer (Olympus AU 5400, Tokyo, Japan) by hospital research services.

**Histopathological Evaluation** Formalin-fixed renal tissue was dehydrated, embedded in paraffin, and sliced into 5-μm-thick sections, which were stained with hematoxylin and eosin by standard methods. Histopathological scoring was performed in a blinded manner. Renal injury was defined as cellular swelling of the tubules, brush border loss, tubular dilatation, tubule cast formation, tubular necrosis, or inflammatory cell infiltration in the inner cortex and outer medullary regions. A scoring scale of 0 to 4 was used: no injury (0), less than 25% (1), less than 50% (2), less than 75% (3), or more than 75% (4). For each section, at least 20 fields were examined under ×400 magnification and the average score was determined as the comprehensive evaluation for each animal.

**Statistical Analysis** Data are expressed as the mean±standard deviation and analyzed using SPSS 14.0 for Windows (SPSS, Chicago, IL, U.S.A.). Histopathological scores were analyzed with Kruskal–Wallis nonparametric ANOVA followed by Dunn’s multiple comparison test. The remaining data were analyzed with one-way ANOVA, followed by a least square difference (LSD) multiple comparison test. Statistical significance was considered as p<0.05.
RESULTS

Isoflurane Preconditioning Improved Renal Function after I/R Injury

Twenty-four hours after renal reperfusion, the I/R group developed significant renal dysfunction indicated by a rise in Scr (98.25±16.17 vs. 47.63±3.96) and BUN (21.56±3.28 vs. 6.40±1.07) levels. In contrast, isoflurane preconditioned rats had a significantly less drastic increase in Scr (76.25±8.17 vs. 98.25±16.17) and BUN (14.15±2.18 vs. 21.56±3.28) levels. This suggests that isoflurane preconditioning exerts a renal protective role against I/R injury (Fig. 1).

Isoflurane Preconditioning Animals Showed Less Tubular Histopathological Damage

Animals subjected to renal I/R injury displayed extensive features of acute tubular damage, including cellular swelling, brush border loss, tubular dilatation, tubule cast formation, and inflammatory cell infiltration in the inner cortex and outer medullary regions. However, isoflurane preconditioned rats had less tubular epithelium and interstitium damage. The tubular damage scores were lower in the ISO+I/R group than those in the I/R group, although no significant difference was observed (2.13±0.38 vs. 1.57±0.36, p=0.23; n=8). As expected, no tubular injury was found in sham controls (Fig. 2).

Preconditioning with Isoflurane Suppressed NF-κB Activation in Kidney

To determine the level of NF-κB activity after renal I/R injury, phosphorylation of IKKα/β and IκBα was assessed for each group by Western blot analysis. The I/R group had significantly higher p-IKKα/β and p-IκBα levels and lower IκBα than those in the sham group. These changes suggest increased NF-κB activity. However, the ISO+I/R group had less IKKα/β and IκBα phosphorylation, and higher renal IκBα protein expression than that in the I/R group (Fig. 3). Collectively, our data indicate that isoflurane is a negative regulator of NF-κB activation following renal I/R injury.

Isoflurane Preconditioning Reduced the Levels of Inflammatory Cytokines

We aimed to investigate whether isoflurane preconditioning affected the levels of inflammatory mediators in serum and kidney. As shown in Fig. 4, there was significantly more HMGB1, IL-1β, and TNF-α in both serum and renal homogenate 24 h after renal reperfusion in the I/R group compared with the sham group. However, the ISO+I/R group had significantly lower inflammatory cytokine production than that in the I/R group. This indicates that isoflurane preconditioning provides renoprotection against renal I/R injury at least partly by attenuating renal and systemic inflammation.

Isoflurane Preconditioning Ameliorated Renal Tubular Apoptosis Induced by I/R

To evaluate the effect of isoflurane on renal apoptosis, TUNEL staining was performed on histological sections from sham, I/R, and ISO+I/R rats. Renal I/R rats had significantly more TUNEL-positive cells in tubules than those in the sham controls. Isoflurane preconditioning alleviated renal apoptosis induced by I/R, as evidenced by fewer TUNEL-positive cells in renal tubules of rats subjected to ISO+I/R than those in controls (2.93±0.81% vs. 13.48±3.57%) (Fig. 5).

Isoflurane Preconditioning Regulated Bcl-2/Bax Ratio

mements 24 h after reperfusion compared with those in the I/R injury group (Fig. 7C).

DISCUSSION

In the present study, we demonstrated that isoflurane preconditioning can protect against renal I/R injury in rats. Specifically, pretreatment with 1.5% isoflurane for 2 h immediately before an I/R challenge significantly attenuated the increase in Scr and BUN. In addition, isoflurane significantly suppressed NF-κB activation and decreased the expression of inflammatory cytokines. We also confirmed that isoflurane preconditioning attenuated tubular apoptosis and regulated the imbalance of Bcl-2/Bax expressions and caspase-3 activation caused by renal I/R injury.

Ioflurane is capable of inducing preconditioning and postconditioning effects in renal I/R injury, which appears to be independent of the effects on systemic blood pressure or renal blood flow.11,12,16 Identifying the mechanisms by which isoflurane mediates renoprotection may be clinically significant during the perioperative period. Here, we reported that the regulation of isoflurane preconditioning on NF-κB-mediated inflammation and dysfunction of the p53-Bax-caspase-3 apoptotic pathway may be the underlying mechanisms involved in renoprotection.

The activation of NF-κB is dependent on the dissociation from its inhibitory protein IκB via the phosphorylation of IKKα/β 13). In the present study, we observed that the canonical NF-κB signaling pathway was activated, as evidenced by marked upregulation of p-IKKα/β and p-IκBα, and degradation of IκBα following I/R challenge. Isoflurane preconditioning suppressed NF-κB activation, which occurred in parallel with reductions in renal injury from I/R both functionally and histologically. Our results were consistent with a previous study in which inhibition targeting IKKα/β using small interfering RNA provided renal protection in a rat model of ischemic AKI.20

HMGB1 is another nuclear factor known to participate in DNA replication and transcriptional activation.21 In addition to its nuclear roles, HMGB1 can be released extracellularly from necrotic or damaged cells and function as an important mediator to trigger local and systemic inflammation.22,23 Reportedly, endogenous HMGB1 expression was upregulated following renal I/R injury, particularly in tubular epithelial cells.24 HMGB1 initiates a signaling cascade leading to activation of NF-κB and upregulation of downstream proinflammatory genes in a mouse model of renal I/R injury, and administration of a neutralizing antibody to HMGB1 provided significant renoprotection.25,26 In agreement with these results, we found that isoflurane preconditioning not only reduced the elevated circulating and renal HMGB1 levels, but also suppressed NF-κB, downstream IL-1β, and TNF-α expression 24 h after reperfusion. Therefore, renoprotection may be mediated by inhibiting NF-κB activation and the production of the proinflammatory cytokines. Previous studies have reported that HMGB1, IL-1β, and TNF-α can act as both the activators and target genes of NF-κB during the inflammatory response.27-29 However, their precise interactions in renal I/R injury remain unclear. We hypothesize that there is not a simple cause–effect relationship between NF-κB activation and excessive cytokine release in the inflammatory cascade induced by renal I/R injury.

Apoptosis is another pathological process involved in renal I/R injury. There are two major apoptosis signaling pathways, namely the intrinsic mitochondrial pathway and the extrinsic death receptor pathway.30 In the mitochondrial pathway, the relative levels of Bax and Bcl-2 have been proposed to play a role in cell survival after ischemia and reperfusion.31,32 Consistent with these studies, our results indicate that 30 min of renal ischemia and 24 h of reperfusion caused a decrease in the ratio of Bcl-2/Bax at both the mRNA and protein levels. Moreover, we have found that caspase-3, an executioner caspase that represents a point of convergence in the intrinsic and extrinsic apoptotic pathways, was also activated following I/R. Isoflurane preconditioning prevented these changes, leading to an increased Bcl-2/Bax ratio and reduced cleaved caspase-3 protein expression, thus inhibiting the increase of TUNEL-positive cells in tubules. Previous studies have revealed that isoflurane attenuate renal I/R injury by modulating leukocyte influx, blunting the protein kinases JNK and ERK activation, upregulating HIF-1α, and activating the SK/SIP signaling pathway.31,32,15,19 Their detailed interaction with the anti-inflammatory and anti-apoptotic actions of isoflurane proposed in our study still needs further investigation.

Our investigation has several limitations. First, we tested only a single concentration (1.5%) for a single duration (2 h) of isoflurane preconditioning. Therefore, dose-dependent protection cannot be determined from this study. However, the dose we used is within the clinical range. Second, our study emphasized the role of isoflurane preconditioning in renal I/R induced cell apoptosis and inflammation pathways. Inflammation after renal I/R injury is a major contributor to renal cell death.15 Nevertheless, we did not investigate the crosstalk between NF-κB-mediated inflammation and the p53-Bax-caspase-3 apoptotic pathway in this complex process. Therefore, further research on this issue is warranted.

In conclusion, we have demonstrated that isoflurane preconditioning at a clinically relevant concentration reduces the degree of renal I/R injury. Inhibition of inflammation and the mitochondrial apoptotic pathway might be involved in the renoprotective actions.
