Glycogen storage disease type Ib (GSD-Ib) is caused by mutations in the glucose-6-phosphate transporter (G6PT) gene, which is involved in glycogen metabolism. Patients with GSD-Ib are known to develop neutropenia as a specific symptom, but the causes remain unclear. To elucidate reduced nicotinamide adenine dinucleotide phosphate (NAD(P)H) oxidase (NOX) 2-associated mechanisms in neutrophil cell membranes, we examined the mechanism of reactive oxygen species (ROS) production after differentiation from HL-60 cells, and the collapse of glycogen metabolism because of G6PT deficiency. ROS production and caspase-3 and -9 activation were observed in G6PT inhibitor-treated neutrophils but not in control cells. Suppression of ROS production by NOX2 inhibitors or protein kinase C (PKC) inhibitors combined with G6PT inhibitor was found to be dependent on the concentration of each inhibitor. Furthermore, ROS production, and caspase-3 and -9 activities were dependent on glucose concentrations. These data indicate that reduced ROS production and suppressed apoptosis in the presence of PKC inhibitors may reflect suppression of PKC-induced NOX2 activation. However, under low glucose conditions, ROS production was reduced and apoptosis was suppressed in neutrophils, suggesting that glucose is a substrate for initiating ROS production. In the present study, the investigation of the pathology of GSD-Ib indicated that a high intracellular glucose level leads to an increase in ROS production by PKC induction and NOX2 activation.

Key words glycogen storage disease type Ib; reactive oxygen species; apoptosis; glucose-6-phosphate transporter; nicotinamide adenine dinucleotide phosphate oxidase; protein kinase C

Glycogen storage disease type Ib (GSD-Ib) is an inborn error of metabolism with an incidence of 1/100,000 and is caused by mutations in the glucose-6-phosphate transporter (G6PT) gene (NM_001467, 11q23), which is involved in glycogen metabolism. 1–4) To date, >80 types of G6PT gene mutations have been reported, and in Japanese patients, the missense mutation (W118R) in the second exon reportedly accounts for >40% of mutations. 5)

G6PT is an endoplasmic reticulum (ER) membrane protein that is involved in glycogen metabolism as a transporter of glucose 6-phosphate (G6P) from the cytoplasm to the ER. 6) The pathology of GSD-Ib includes hepatomegaly and renal swelling caused by accumulation of large quantities of glycogen in the liver and kidneys. Deficiencies of the G6Pase system result in decreased conversion of G6P into glucose, leading to tissue compression by glycogen and subsequent liver and kidney dysfunction. In addition, because majority of glucose is produced by hydrolysis of G6P during glycogenolysis and glyconeogenesis, deficiencies of the G6Pase system cause hypoglycemia, which compels patients with GSD-I to maintain blood glucose levels by constantly ingesting glucose or its polymers. Subsequently, decreased ratios of blood insulin to glucagon promote fatty acid release from fat tissues, which causes hyperlipidemia and fatty liver disease.

In addition, patients with GSD-Ib develop neutropenia as a specific symptom, although the mechanisms remain to be elucidated. Previous reports by Kuipers et al. 7) show that oxidative stress and apoptosis are significantly increased in neutrophils of patients with GSD-Ib and G6PT+/− mice compared with healthy subjects and G6PT−/− mice, respectively. Increased apoptosis is believed to be caused by oxidative stress. 8) Accordingly, treatment of patients with GSD-Ib with the vitamin E significantly improves neutropenia because of its antioxidant activity. Several reports describe the causal role of oxidative stress in neutropenic patients with GSD-Ib. However, few reports elucidate mechanisms associated with the production of reactive oxygen species (ROS). Leuzzi et al. 9) identified a reduced nicotinamide adenine dinucleotide phosphate (NAD(P)H) oxidase (NOX) 2-mediated ROS production pathway in GSD-Ib neutrophils, and showed that inhibition of G6PT led to NOX2 activation, and that a NOX2 inhibitor suppressed apoptosis. 11) Whereas this report demonstrated the role of NOX2 in ROS production, the role of G6PT deficiency in patients with GSD-Ib was not described.

In the present study, we determined the mechanisms by which collapse of glycogen metabolism because of G6PT deficiency results in the production of ROS. In this study, cytoplasmic neutrophil NOX2 activation was characterized in HL-60 human premyeloid leukemia-derived cells and the causes of GSD-Ib-mediated neutropenia were elucidated.

MATERIALS AND METHODS

Cell Culture HL-60 cells were differentiated into neutrophils by addition of 1.25% dimethyl sulfoxide (DMSO) to
RPMI1640 medium containing 10% fetal bovine serum (FBS), as described by Leuzzi et al. Subsequently, on Day 2 of differentiation, the cells were incubated with the G6PT inhibitor 4,4-diisothiocyanostilbene-2,2-disulfonic acid (DIDS), and were harvested on Day 4 of differentiation for use in experiments. Control cells were differentiated using 1.25% DMSO, but were cultured for 4d without DIDS.

**Determination of ROS Production Using L-012** DIDS-treated neutrophils were washed in phosphate buffered saline (PBS) and were resuspended in RPMI1640 medium at 1×10⁵ cells per 600 µL. Subsequently, 600 µL cell suspensions were treated with 2 µL of 20 mM 8-amino-5-chloro-7-phenylpyridol[3,4-d]pyridazine-1,4-(2H,3H)dione sodium salt (L-012) with or without 6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid (Trolox C), diphenyliodonium chloride (DPI), apocynin, 3-(1-(3-imidazol-1-ylpropyl)-1H-indol-3-yl)-4-anilino-1H-pyrrole-2,5-dione (IYIAP), staurosporine, or chelerythrine. DMSO was used as a vehicle for all cell

![Fig. 1. Effects of DIDS on ROS Production and Apoptosis in Neutrophils](image)

Neutrophils were incubated with 1, 10, 100, or 500 µM DIDS on Day 2 of differentiation and were cultured until Day 4. (A) Time-dependent ROS production; (B) ROS production on Day 4 of differentiation; (C, D) Caspase-3 and -9 activities on Day 4; Apoptosis marker proteins (E) Bax, (F) Smac/Diablo, and (G) Omi/HtrA2. Cells in E–G were treated with 100 µM DIDS; N, DIDS-untreated cells; D, DIDS-treated cells; red, apoptosis marker proteins; blue, DAPI. Results are expressed as the mean±S.E. of 4–6 independent experiments. Untreated neutrophils (None) were given a value of 1; E–G; *p<0.05 vs. untreated neutrophils; scale bar 50 µm.
treatments. Thus, control cells were treated with DMSO and DIDS. Luminol ROS assays were performed using L-012 with a luminometer (Lumat LB 9507, Berthold Technologies, Bad Wildbad, Germany).

Effects of Glucose Concentrations on ROS Production in DIDS-Treated Neutrophils Neutrophils were cultured in RPMI1640 medium containing 1, 2, 3.3, 5, or 10 mM glucose, 10% FBS, and 1.25% DMSO (Day 0), and 100 μM DIDS was added on Day 2. Cells were harvested on Day 4 and ROS production was measured using a luminometer. Control cells were cultured in RPMI1640 containing 10 mM glucose, 10% FBS, and 1.25% DMSO, without DIDS.

Measurement of NOX2 Activity on Cell Membranes Cells were homogenized in cell-disruption buffer for 1 min using a homogenizer. The homogenate was then centrifuged at 9000×g for 20 min and cell membrane fractions were collected by centrifugation of supernatants at 100000×g for 60 min. Supernatant-buffer interfaces were harvested as cell membrane fractions. All operations were performed on ice. Final protein concentrations were adjusted to 0.2 mg protein/mL according to the manufacturer’s instructions. NOX2 activity was evaluated by measuring the fluorescence of L-012 after reaction with ROS, which was produced by the NOX2 coenzyme NAD(P)H. The reaction mixture contained 550 μL of RPMI1640, 50 μL of 0.2 mg protein/mL cell membrane fraction, and 2 μL of 20 mM L-012 with or without 5 μL of 24 mM NAD(P)H. Luminol reactions with L-012 were monitored using a luminometer.

Caspase-3 and -9 Activities Caspase-3 and -9 activities were measured using commercially available kits according

Fig. 2. Examination of ROS Production in DIDS-Treated Neutrophils

(A) DIDS-treated neutrophils were incubated with the NOX2 inhibitors DPI or apocynin, or with the PKC inhibitors IYIAP, staurosporine, or chelerythrine. ROS production after treatment with DPI (B), or IYIAP (C); NOX2 activity in cell membranes (D) was determined in the presence of 200 mM NADPH or NADH in untreated neutrophils or (II) DIDS-treated neutrophils. Results are expressed as the mean±S.E. of 4–6 independent experiments. Untreated neutrophils (control) were given a value of 1; *p<0.05, **p<0.01 vs. untreated neutrophils; †p<0.05, ‡p<0.01 vs. 100 μM DIDS-treated neutrophils.
to the manufacturer’s instructions. These measurements were based on spectrophotometric detection of the chromophore p-nitroanilide (pNA) after cleavage from the labeled substrates DEVD-pNA or LEHD-pNA. Cells were resuspended in 50 µL of cell-disruption buffer and were subjected to three freeze-thaw cycles. After 20 min incubation on ice, suspensions were centrifuged at 10000 × g for 1 min at 4°C and supernatants were used as cytoplasm fractions. Absorbance of the chromogen pNA was measured at 405 nm using a microplate reader according to the manufacturer’s instructions.

**Measurement of Apoptosis Marker Proteins** Neutrophils were seeded into 96-well plates at a concentration of 1×10^4 cells/well. After treatments, cells were harvested by centrifugation at 1000 rpm for 5 min. Cells were then fixed in 100% methanol and were washed 3 times in PBS. Cells were incubated overnight at 4°C with the following primary antibodies, diluted in PBS: Bax (1:100), Smac/Diablo (1:100), and Omi/HtrA2 (1:100). Cells were then washed 3 times in PBS and incubated with Alexa Fluor 568-conjugated anti-mouse immunoglobulin G (IgG) (1:200) or rabbit IgG (1:200) for 60 min at room temperature. Unbound secondary antibody was removed by washing 3 times in PBS. Sample fluorescence was visualized using a fluorescence microscope, and was quantified using a fluorescence microplate-reader with excitation and emission wavelengths of 584 and 612 nm, respectively.

**RESULTS**

**Effects of DIDS Treatment on ROS Production** ROS production in neutrophils was evaluated after treatment with the G6PT inhibitor DIDS. Treatment with DIDS stimulated ROS production in neutrophils in a time-dependent manner (Fig. 1A). On Day 4 of differentiation, ROS production was increased by 4.0-, 6.3-, 23.7-, and 37.4-fold, in the presence of 1, 10, 100, and 500 µM DIDS, respectively (Fig. 1B).

**Effects of DIDS Treatments on Apoptosis** Cells were cultured under the same conditions as for ROS assays and were harvested on Day 4. Caspase-3 and -9 activities were increased in a DIDS concentration-dependent manner (Figs. 1C, D). Figures 1E–G show 4-, 2-, and 2-fold increased immunostaining of the apoptosis marker proteins Bax, Smac/Diablo, and Omi/HtrA2, respectively, in 100 µM DIDS-treated neutrophils compared with untreated neutrophils.

**Examination of the ROS Production Pathway** ROS production was increased 30-fold in DIDS-treated cells compared with control cells. Concentration-dependent suppression of ROS production was observed after treatments with the NOX2 inhibitors DPI and apocynin, and the PKC inhibitors IYIAP, staurosporine, and chelerythrine (Fig. 2A). In addition, treatments with 0.1, 1, 5, and 10 µM DPI reduced ROS production by 35.1%, 25.4%, 20.2%, and 3.5%, respectively, compared with DIDS-treated cells (Fig. 2B). Addition of 0.4, 2, 4, 20, and 40 nM IYIAP to DIDS-treated cells reduced ROS production to 89.3%, 41.3%, 28.8%, 16.5%, and 7.6%, respectively.
ROS Production following Activation of Cell Membrane NOX2. ROS production in cell membrane fractions was determined after addition of NAD(P)H. No significant changes in ROS production were observed in the presence of 200µM NADH or 200µM NADPH to control cells. In contrast, ROS production was significantly increased by 13- or 14-fold after addition of NADH or NADPH, respectively, in comparison with DIDS-treated control cells (Fig. 2D).

Effects of ROS Inhibitors on Apoptosis. Caspase-3 and -9 activities in cells harvested on Day 4 were increased 4- and 5-fold in DIDS-treated cells compared with untreated control cells. Addition of Trolox C, IYIAP, or DPI reduced caspase-3 and -9 activities to 23.0%, 11.0%, or 6.9%, and 60.7%, 63.5%, or 55.8%, respectively, compared with DIDS-treated control cells (Figs. 3A, B).

Figures 3C–E show the expression of the apoptosis marker proteins Bax, Smac/Diablo, and Omi/HtrA2 in DIDS-treated cells. Addition of Trolox C, IYIAP, or DPI reduced Bax, Smac/Diablo, and Omi/HtrA2 protein expression to 48.4%, 31.2%, or 23.9%, 55.3%, 46.3%, or 22.6%, and 59.6%, 38.6%, or 29.7%, respectively, compared with DIDS-treated control cells (Figs. 3C–E).

Effects of Glucose Concentrations on ROS Production in DIDS-Treated Neutrophils. ROS production in neutrophils was evaluated after stimulation with DIDS in the presence of various glucose concentrations. DIDS-treated neutrophils produced ROS in a glucose concentration- and time-dependent manner (Fig. 4).
manner (Fig. 4A). Moreover, reduced glucose concentrations stoichiometrically suppressed ROS production (Figs. 4A, B).

On Day 4, cell membrane NOX2 activity in the presence of 200 µM NADPH was dependent on glucose concentrations (Fig. 4C).

**Effects of Glucose Concentration on Caspase Activities in DIDS-Treated Neutrophils**

On Day 4, caspase activities were significantly increased in DIDS-treated cells compared with control cells. However, caspase-3 and -9 activities were shown to be dependent on glucose concentrations (Figs. 4D, E). Specifically, supplementation of DIDS-treated neutrophils with 5, 3.3, 2, or 1 mM glucose reduced caspase-3 activity to 66.3%, 53.9%, 49.2%, or 40.5%, respectively, in comparison with that in the presence of 10 mM glucose (Fig. 4D). Under the same conditions, caspase-9 activity was reduced to 75.2%, 63.9%, 37.3%, and 46.3%, respectively (Fig. 4E).

**DISCUSSION**

Neutrophils of patients and mice with GSD-Ib produce ROS without external stimuli. To prepare a model of GSD-Ib neutrophils, we induced differentiation of HL-60 cells to neutrophils using the culture conditions described above and added the G6PT inhibitor, DIDS, on Day 2 of differentiation. ROS production was significantly higher in cells exposed to DIDS compared with control cells, and increased in a time- and concentration-dependent manner (Figs. 1A, B).

Caspace cysteine proteases play central roles in signal transduction during apoptosis. Accordingly, caspase-3 and -9 activities and ROS production were increased in DIDS-treated differentiated HL-60 cells in a concentration-dependent manner (Figs. 1C, D). In addition, the apoptosis marker proteins Bax, Smac/Diablo, and Omi/HtrA2 were increased in these cells, as shown in immunostaining experiments (Figs. 1E–G). Bax is a member of the pro-apoptotic Bcl-2 family, and is involved in the release of mitochondrial cytochrome c. Smac/Diablo and Omi/HtrA2 suppress inhibition of caspase by XIAP and promote caspase activation. As shown in Figs. 1E–G, DIDS-treated neutrophils had increased immunohistochemical florescence of these apoptosis marker proteins compared with untreated cells, indicating that DIDS-treated HL-60 cells are an appropriate model of GSD-Ib.

ROS production by NOX2 has been demonstrated in vivo. However, NOX2 is inactive in the absence of various soluble proteins. NOX2 plays a central role in phagocytic and bactericidal mechanisms of neutrophils, produces ROS by transferring an electron from cytoplasmic NAD(P)H to extracellular oxygen, and transduces signals following binding with p67
