Received April 11, 2016; accepted September 1, 2016; advance publication released online September 7, 2016

We recently demonstrated that activation of spinal sigma-1 receptors (Sig-1Rs) induces pain hypersensitivity via the activation of neuronal nitric oxide synthase (nNOS) and nicotinamide adenine dinucleotide phosphate (NADPH) oxidase 2 (Nox2). However, the potential direct interaction between nNOS-derived nitric oxide (NO) and Nox2-derived reactive oxygen species (ROS) is poorly understood, particularly with respect to the potentiation of N-methyl-d-aspartate (NMDA) receptor activity in the spinal cord associated with the development of central sensitization. Thus, the main purpose of this study was to investigate whether Sig-1R-induced and nNOS-derived NO modulates spinal Nox2 activation leading to an increase in ROS production and ultimately to the potentiation of NMDA receptor activity and pain hypersensitivity. Intrathecal pretreatment with the nNOS inhibitor, 7-nitroindazole or with the Nox inhibitor, apocynin significantly inhibited the mechanical and thermal hypersensitivity induced by intrathecal administration of the Sig-1R agonist, 2-(4-morpholinethyl)-1-phenylcyclohexanecarboxylate hydrochloride (PRE084). Conversely, pretreatment with 5,10,15,20-tetrakis-(4-sulphonatophenyl)-porphyrinato iron(III) (FeTPPS; a scavenger of peroxynitrite, a toxic reaction product of NO and superoxide) had no effect on the PRE084-induced pain hypersensitivity. Pretreatment with 7-nitroindazole significantly reduced the PRE084-induced increase in Nox2 activity and concomitant ROS production in the lumbar spinal cord dorsal horn, whereas apocynin did not alter the PRE084-induced changes in nNOS phosphorylation. On the other hand pretreatment with apocynin suppressed the PRE084-induced increase in the protein kinase C (PKC)-dependent phosphorylation of NMDA receptor GluN1 subunit (pGluN1) at Ser896 site in the dorsal horn. These findings demonstrate that spinal Sig-1R-induced pain hypersensitivity is mediated by nNOS activation, which leads to an increase in Nox2 activity ultimately resulting in a ROS-induced increase in PKC-dependent pGluN1 expression.

Key words neuronal nitric oxide synthase; sigma-1 receptor; pain hypersensitivity; nicotinamide adenine dinucleotide phosphate oxidase 2; phosphorylation

Regular Article

Nitric oxide (NO) is involved in many pathophysiological processes, including the important role that it serves as a neurotransmitter/neuromodulator involved in nociceptive processes in the spinal cord dorsal horn. It has been well demonstrated that NO is a diffusible gas synthesized in biological systems by enzymes known as nitric oxide synthases (NOS) (neuronal/nNOS, inducible/iNOS, or endothelial/eNOS). Interestingly, nNOS co-localizes with N-methyl-d-aspartate (NMDA) receptor and is functionally coupled to this glutamate receptor subtype via binding with postsynaptic density protein-95. Several studies suggest that activation of NMDA receptors modulates spinal nociceptive transmission via nNOS, which is dephosphorylated and activated by the Ca\(^{2+}\)/calmodulin (CaM)-dependent phosphatase calcineurin, resulting from Ca\(^{2+}\) influx through NMDA receptors. In a previous study, we showed that blockade of spinal nNOS using intrathecal (i.t.) administration of the nNOS inhibitor, 7-nitroindazole, reduces sigma-1 receptor (Sig-1R)-induced pain hypersensitivity and suppresses the Sig-1R-induced increase in protein kinase C (PKC)-dependent phosphorylation of GluN1 subunit (pGluN1) resulting in the potentiation of NMDA receptor function. These findings raise the possibility that the action of NO on nociceptive transmission at spinal synapses could be closely linked to Sig-1R-induced functional activation of NMDA receptors. It has been suggested that reactive oxygen species (ROS) play an important role in ‘central sensitization,’ a critical mechanism underlying persistent pain, via increases in NMDA receptor phosphorylation in the spinal cord dorsal horn. ROS can be generated by activation of the nicotinamide adenine dinucleotide phosphate (NADPH) oxidase (Nox) enzyme. Among six homologs, the NADPH oxidase 2 (Nox2) isoform has been indicated as the main source of ROS in neurons, which produces superoxide following neuronal NMDA receptor activation. Nox2 is a highly regulated membrane bound enzyme complex that is composed of membrane-bound subunits (p22phox and gp91phox) and cytosolic subunits (p40phox, p47phox, and p67phox) as well as the small guanosine triphosphatase (GTPase) Rac. The cytosolic components translocate to the cell membrane in order to form a functional active enzyme complex. In particular p47phox has an important role in both translocation and assembly, by which Nox enzyme activation is initiated. In a previous study, we demonstrated that spinal Sig-1R activation increases p47phox translocation to the membrane fraction and concomitant ROS production. However, it remains unclear whether Nox2-derived ROS mediates Sig-1R-induced potentiation of NMDA receptor function.

The activation of spinal Sig-1Rs has been considered to play an important role in pain sensitization. As previously described, Sig-1R-induced pain is closely associated with nNOS activation as well as Nox2-derived ROS production and both ROS and NO participate in NMDA receptor signaling. However, the hypothetical interaction between these two signaling pathways is poorly understood, particularly as it relates to the potentiation of NMDA receptor activity in the spinal cord. The main goal of this study was to investigate whether nNOS-derived NO induced by Sig-1R stimulation plays an important role in spinal Nox2 activation leading to increases in ROS production and the potentiation of NMDA receptor activity and ultimately resulting in pain hypersensitivity. In this regard, the present study specifically examined whether: (1) nNOS and Nox activation or p38 mitogen-activated protein kinase (p38 MAPK), a reaction product of NO and superoxide, mediates Sig-1R-induced pain hypersensitivity; (2) nNOS-derived NO induced by Sig-1R activation increases Nox2 activity and concomitant ROS production in the spinal cord dorsal horn; and finally, (3) Nox-derived ROS contributes to the increase in phosphorylation of NMDA receptors.

MATERIALS AND METHODS

Experimental Animals Male ICR mice (20–25 g) were purchased from the Laboratory Animal Center of Seoul National University (Seoul, Republic of Korea) and used for the present study. Mice had free access to food and water and were kept in temperature and light controlled rooms (23°C, 12/12 h light/dark cycle with lights on at 08:00) for at least 3 d prior to the beginning of each experiment. The experimental protocols for animal usage were reviewed and approved by the SNU Animal Care and Use Committee and conform to NIH guidelines (1985).

Drugs and Intrathecal (i.t.) Administration The following drugs were used: 2-(4-morpholinethyl)-phenylethylcyclohexanecarboxylate (PRE084; PRE, 3 nmol), a Sig-1R agonist; 7-nitroindazole (7-NI, 200 nmol), a selective nNOS inhibitor; 6-(1-iminoethyl)lysine dihydrochloride (L-NIL, 20 nmol), a selective iNOS inhibitor; diphenyleneiodonium chloride (DPI, 6 nmol), an eNOS inhibitor; 4'-hydroxy-3' methoxyacetophenone (apocynin, 100 nmol), a NADPH oxidase inhibitor; 5,10,15,20-tetrakis-(4-sulphonatophenyl)-porphyrinato iron(III) (FeTPPS, 3 nmol), a peroxynitrite scavenger; chelerythrine (CHE, 1 nmol), a PKC inhibitor. Apocynin, 7-NI and L-NIL were supplied by Sigma-Aldrich (St. Louis, MO, U.S.A.) and DPI by MP Biomedicals (OH, U.S.A.). PRE and CHE were obtained from Tocris Cookson Ltd. (Bristol, U.K.) and FeTPPS from Calbiochem (San Diego, CA, U.S.A.). The doses of all drugs were selected based on or slightly modified from established doses previously used in the literature including those used in previous studies from our laboratories. PRE, L-NIL and FeTPPS were dissolved in physiological saline. 7-NI was dissolved in 5% dimethyl sulfoxide (DMSO) in Corn oil. DPI, apocynin and CHE were dissolved in 5% DMSO in physiological saline. The control group received an injection of vehicle.

All drugs were dissolved in 5 µL of vehicle and were administered intrathecal 10 min before PRE injection. Intrathecal injections were performed at the L4-L6 intervertebral space of unanesthetized mice using a Hamilton syringe connected to a 30-gauge needle as previously described by Hylden and Wilcox. Animals were randomly assigned to experimental groups and subsequent drug treatment and analysis were performed blindly.

Mechanical and Thermal Hypersensitivity Test Pain hypersensitivity was measured before and at 30, 60 and 120 min after administration of the Sig-1R agonist, PRE (or vehicle) in all groups of mice (n=5 mice/group). Sensitization to innocuous mechanical stimulation was examined using a von Frey filament (North Coast Medical, Morgan Hill, CA, U.S.A.) as previously described. Based on this previous study, the 0.16 g von Frey filament was selected for testing and was applied 10 times to each hind paw with each application separated by 10 s intervals. Then, the number of paw withdrawal responses was counted. The results of mechanical response testing in each experimental animal were expressed as a percent paw withdrawal frequency (PWF, %), which represented the percentage of paw withdrawals out of a maximum of 20 (right hind paw-10 and left hind paw-10).

Sensitization to noxious heat stimulation was examined with a hot-plate apparatus (Model-35100, Ugo Basile, Come- rio, Italy). The temperature of the hot plate was maintained at 55±0.5°C. Animals were placed into an acrylic cylinder (20 cm in diameter, 25 cm high) on the heated surface, and the time between placement and the initial shaking, licking or lifting of their hind paws or jumping (whichever occurred first), was recorded as the latency responses (s). The test was duplicated in each animal, and the mean latency response was calculated. Cutoff time in the absence of a response was set at 20 s to minimize potential tissue damage.

Western Blot Assay Mice were deeply anesthetized with 3% isoflurane 30 min after i.t. injection of PRE084 (n=6 mice/group). The Western blot assay was performed as described in our previous report. The spinal cord was extracted by pressure expulsion with air into an ice-cooled, saline-filled glass dish. Following expulsion, the dorsal horns from the L4-L6 spinal segments were homogenized in lysis buffer (20 mM Tris–HCl, 10 mM ethylene glycol bis(2-aminoethyl ether)-N,N′,N″,N″′-tetraacetic acid (EGTA), 2 mM ethylenediaminetetraacetic acid (EDTA), pH 7.4, and proteinase inhibitors), and homogenates were centrifuged at 15000 rpm for 40 min at 4°C. For preparation of the membrane fraction, the pellet was re-suspended in lysis buffer containing 1% Triton X-100. For preparation of total proteins, the spinal cord dorsal horns were homogenized first in lysis buffer containing 1% Triton X-100. Homogenates were subsequently centrifuged using the same method as described above and the supernatant was used for Western blot analysis.

The total amount of protein in each sample was determined using the Bradford dye assay. Spinal cord homogenates (25–35 µg protein) were separated using 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to nitrocellulose membrane. After the blots had been washed with TBST (10 mM Tris–HCl, pH 7.6, 150 mM NaCl, and 0.05% Tween-20), the membranes were blocked with 5% skimmed milk for 1 h at room temperature and incubated at 4°C overnight with a primary antibody specific for p47phox (rabbit polyclonal anti-p47phox antibody, 1:1k, cat# 14015, Santa Cruz Biotechnology Inc.), PKC-dependent pGluN1 (rabbit polyclonal anti-pGluN1 Ser896 antibody, 1:1k, cat# ABN88, Millipore Co., U.S.A.) or β-actin (mouse monoclonal anti-β-actin antibody, 1:5k, cat# 47778, Santa Cruz.
Biotechnology Inc., U.S.A.). After washing with TBST, membranes were incubated for 4h with horseradish peroxidase (HRP)-conjugated anti-rabbit or anti-mouse antibody (1:10k, Santa Cruz Biotechnology Inc.). The bands were visualized with enhanced chemiluminescence (Amersham Biosciences, Buckinghamshire, U.K.). The positive pixel area of specific bands was measured with a computer-assisted image analysis system and normalized against the corresponding β-actin loading control bands. To analyze activation of Nox2, the ratio of the membrane fraction (M) of p47phox to the total protein (T) of p47phox expression was calculated. The value of the ratio of p47phox (M) to p47phox (T) expression in the control groups was set at 100%. Thus, the percent change in p47phox (M) to p47phox (T) expression was examined for each group. For analysis of pGluN1 expression, the value of the control groups was set at 100% and, then, the percent change relative to the control groups was calculated for each group.

**Immunohistochemistry** Thirty minutes after i.t. injection of PRE084 mice were anesthetized with 3% isoflurane and spinal cord immunohistochemistry was performed as described in our previous report (n=5–7 mice/group). Briefly mice were perfused transcardially with calcium-free Tyrode's solution followed by 200mL of a fixative containing 4% paraformaldehyde and 0.2% picric acid in 0.1M phosphate buffer (pH 7.4). The spinal cords were removed immediately after perfusion, post-fixed in the identical fixative overnight and then placed in 30% sucrose in phosphate buffered saline (PBS) (pH 7.4) for 24h at 4°C. Serial transverse sections (40µm) of the spinal cord were cut using a cryostat (Microm, Germany). L4–6 spinal tissue sections were incubated at 4°C with a primary antibody specific for phosphorylated form of nNOS (p-nNOS) (rabbit polyclonal anti-pnNOS Ser847 antibody, 1:3k, cat# ab66650, Abcam Inc.) or PKC-dependent pGluN1 (rabbit polyclonal anti-pGluN1 Ser896 antibody, 1:1k, cat# 06–640, Upstate Biotechnology). The primary antibodies were detected by incubating the tissue in biotinylated anti-rabbit immunoglobulin G (IgG) (1:200, cat# BA-1000; Vector Laboratories, Inc.) for 1h at r.t. Then following several rinses, the tissue was further incubated in avidin-biotin–peroxidase complex (ABC) for 1h. Visualization of the ABC complex was performed using 3,3-diaminobenzidine (Sigma) and the 3,3-diaminobenzidine reaction was subsequently intensified with 0.2% nickel chloride.

**Detection of in Situ Generation of ROS** To detect the in situ generation of ROS in the spinal cord, dihydroethidium (DHE) staining was performed as previously described (n=4 mice/group). Thirty minutes after i.t. injection of PRE084 mice were anesthetized with 3% isoflurane and perfused transcardially with calcium-free Tyrode’s solution. The lumbar spinal cord from each mouse was collected and prepared in Tissue-Tek O.C.T. compound (Sakura Finetechnical Co., Japan) and then frozen immediately in liquid nitrogen. Spinal cord segments were cut into 40µm thick transverse sections and placed on a glass slide. DHE (1nM, cat# D-1168, Invitrogen) was topically applied to each section and cover-slipped. Slides were incubated in a dark, humidified chamber at 37°C for 30min. DHE is oxidized by superoxide to ethidium bromide, which binds to the DNA and emits red fluorescence.

**Image Analysis** Tissue sections were first examined under darkfield microscopy at 4× magnification to determine the gray matter landmarks and to distinguish the laminae of the dorsal horn as defined by Abbadie and Besson. The immunostaining of pNOS and pGluN1 in the spinal cord was then examined under a brightfield microscope. The red fluorescence associated with DHE staining was detected through a 580nm long-pass filter and examined using a fluorescence microscope (Zeiss Axioscope, Halbleerloos, Germany). Three to five spinal cord sections from the L4-L6 spinal cord segments were randomly selected from each animal, and subsequently scanned using a cooled CCD camera (Micromax Kodak 1317; Princeton Instruments, AZ, U.S.A.) connected to a computer-assisted image analysis system (Metamorph version 6.3r2; Molecular Devices Corporation, PA, U.S.A.). To maintain a constant threshold for each immunostained image and to compensate for subtle variability of the immunostaining, we only counted cells that were at least 70% darker than the average gray level of each image after background subtraction and shading correction. The average number of pNOS-immunoreactive (ir) or pGluN1-ir cells and the average intensity of DHE fluorescence per section from each animal were obtained in the following three spinal cord dorsal horn regions (as defined by Abbadie and Besson): 1) the superficial dorsal horn (DH, laminae I–II); 2) the nucleus proprius (NP, laminae III–IV); and 3) the neck region (NECK, laminae V–VI).

**Measurement of NO in the Spinal Cord** NO was determined in the spinal cord dorsal horns from the lumbar enlargement using a nitric oxide detection kit (cat# ADI-917-020, Enzo Life Sciences Inc., U.S.A.). This nitric oxide (total), detection kit is based on the enzymatic conversion of nitrate to nitrite by the enzyme nitrate reductase, followed by the Griess reaction to form a colored azo dye product. Animals (n=4–6 mice/group) were euthanized 30min after PRE084 injection. Mice were deeply anesthetized with 3% isoflurane in a mixture of N2O/O2 gas and perfused transcardially with calcium-free Tyrode’s solution. The isolated spinal cords were homogenized in PBS by sonication. Homogenates were subsequently centrifuged at 4000×g for 10min at 4°C and, then, the supernatant was used for nitric oxide detection following the manufacturer’s recommendation.

**Statistical Analysis** Data are expressed as the mean±standard error of the mean (S.E.M.) Statistical analyses were performed by using Prism 5.0 (Graph Pad Software, San Diego, U.S.A.). Repeated measures two-way ANOVA was performed to determine differences in the data from the time course changes in pain hypersensitivity shown in Fig. 2. Statistical analyses for other data were performed with one-way ANOVA. Post-hoc analysis was performed using the Bonferroni’s multiple comparison test in order to determine the p-value among experimental groups. ANOVA values and degrees of freedom were shown in Supplementary materials Table S1 and S2. A p<0.05 was considered statistically significant.

**RESULTS**

Sig-1R Activation Increases NO Production in the Spinal Cord Dorsal Horn through nNOS Activation To investigate whether spinal Sig-1R activation modulates NO
production in the spinal cord, we examined the effect of i.t. administration of the Sig-1R agonist, PRE084 on NO levels in the dorsal horn by examining changes in nitrate concentration. Intrathecal administration of PRE084 (3 nmol) significantly increased NO production in the dorsal horn 30 min after PRE084 injection as compared with that of the PRE084-treated group that received vehicle (Figs. 2A, B; *p<0.05, **p<0.01, ***p<0.001 vs. VEH+PRE). To further investigate whether the peroxynitrite, which is synthesized by the interaction of NO and superoxide, contributes to this pain hypersensitivity, we next examined the effect of i.t. pretreatment with a peroxynitrite scavenger on the PRE084-induced pain hypersensitivity. As shown in Figs. 2A and B, i.t. pretreatment with the peroxynitrite scavenger, FeTPPS (3 nmol) had no effect on the PRE084-induced pain hypersensitivity as compared with that of the PRE084-treated group (Figs. 2A, B; *p<0.05, **p<0.01, ***p<0.001 vs. VEH+PRE; non-significance vs. VEH+PRE).

The i.t. injection of these inhibitors alone (7-NI+VEH, APO+VEH, FeTPPS+VEH), in the absence of PRE, did not affect pain hypersensitivity in comparison to the VEH+VEH group (Figs. 2C, D).

Sig-1R-Induced nNOS Activation Increases ROS Production and Nox2 Activity in the Spinal Cord Dorsal Horn

To investigate whether Sig-1R-induced NO modulates ROS production, we examined the effects of i.t. pretreatment with an nNOS inhibitor on the Sig-IR-induced increase in ROS production in the dorsal horn by measuring the fluorescence of DHE staining. As illustrated in Fig. 3, i.t. pretreatment with the nNOS inhibitor, 7-NI (200 nmol, 7-NI+PRE) significantly inhibited the PRE084-induced increase in ROS production in the SDH (laminae I–II) region of the lumbar spinal cord dorsal horn (Figs. 3A–D; *p<0.01 vs. VEH+VEH, **p<0.05 vs. VEH+PRE). The i.t. injection of this inhibitor alone (7-NI+VEH), in the absence of PRE, did not affect ROS production in comparison to the VEH+VEH group.

To investigate whether the NO induced by Sig-1R stimulation modulated Nox2 activation, we next examined the effects of i.t. pretreatment with 7-NI on the Sig-1R-induced increase in Nox2 activation in the dorsal horn by measuring the expression of the Nox2 subunit p47phox using a Western blot assay. Since an increase in the membrane fraction of the p47phox represents an increase in the active forms of the Nox2 enzyme and since the total protein expression of p47phox did not change following PRE084 injection, then the increase in the ratio of membrane (M) to total (T) protein expression of p47phox is considered to reflect an increase in the active forms of Nox2. As illustrated in Fig. 3E, i.t. pretreatment with 7-NI (200 nmol, 7-NI+PRE) significantly inhibited the PRE084-induced increase in the ratio of membrane to total protein expression of p47phox in the lumbar spinal cord dorsal horn (Fig. 3E; *p<0.05 vs. VEH+VEH, **p<0.05 vs. VEH+PRE). The i.t. injection of this inhibitor alone (7-NI+VEH), in the absence of PRE, did not affect spinal Nox2 activation in comparison to the VEH+VEH group.

Sig-1R-Induced Nox Activation Has No Effect on the Number of pnNOS-ir Cells and NO Concentration in the Spinal Cord Dorsal Horn

Since phosphorylation of nNOS (pnNOS) at serine 847 (Ser847) inhibits nNOS activity,5,6 a decrease in the pnNOS expression is considered to reflect an increase in the active forms of nNOS. The changes in the expression of pnNOS in the spinal cord dorsal horn were measured by using an immunohistochemistry. Intrathecal injection of PRE084 (3 nmol, VEH+PRE) significantly decreased the phosphorylation of nNOS (as evidenced by a decrease in pnNOS-ir cells) in the SDH (laminae I–II) and

**Fig. 1.** The Effects of i.t. Administration of the nNOS Inhibitor (7-Nitroindazole, 7-NI, 200 nmol), the iNOS Inhibitor (l-NIL, 20 nmol) and the eNOS Inhibitor (DPI, 6 nmol) on the PRE084 (PRE, 3 nmol)-Induced Increase in the Total NO Concentration in the Lumbar Spinal Cord Dorsal Horn

Total NO concentration was measured indirectly as the concentration of its stable decomposition product nitrate in the spinal cord dorsal horns. Intrathecal administration of 7-NI, l-NIL or DPI was performed 10 min before PRE injection and the lumbar dorsal horn was sampled 30 min after PRE injection. n = 4 mice/group. ***p<0.001 vs. VEH+VEH; ###p<0.001 vs. VEH+PRE; n.s., non-significance.
NP regions (laminae III–IV) of the lumbar spinal cord dorsal horn (Figs. 4A, B; *p < 0.05, ***p < 0.001 vs. VEH+VEH). This decrease was not blocked by i.t. pretreatment with the Nox inhibitor, apocynin (100 nmol, APO+PRE) (*p < 0.05, ***p < 0.001 vs. VEH+VEH). The i.t. injection of this inhibitor alone (APO+VEH), in the absence of PRE, did not affect the number of pnNOS-ir cells in comparison to the VEH+VEH group. We further confirmed changes in spinal NO production by examining changes in nitrate concentration. PRE084 (3 nmol, VEH+PRE) significantly increased total NO levels as compared with that of the vehicle-treated group, while this increase was not suppressed by pretreatment with APO (Fig. 4C; *p < 0.05 vs. VEH+VEH, non-significance vs. VEH+PRE).

Sig-1R-Induced Nox Activation Increases pGluN1 Expression in the Spinal Cord Dorsal Horn Intrathecal administration of PRE084 (3 nmol, VEH+PRE) significantly increased the number of cells in the SDH (laminae I–II), NP (laminae III–IV) and NECK regions (laminae V–VI) of the lumbar spinal cord dorsal horn that were immunoreactive for PKC-dependent phosphorylation (at the Ser896 site) of the NMDA receptor GluN1 subunit (pGluN1) (Figs. 5A, B; ***p < 0.001 vs. VEH+VEH). Intrathecal pretreatment with the Nox inhibitor, apocynin (100 nmol, APO+PRE) prior to PRE084 administration, dramatically suppressed this PRE084-induced increase in the number of PKC-dependent pGluN1-ir cells in the spinal cord dorsal horn, particularly in the NP and NECK regions (Figs. 5A, B; *p < 0.05, ***p < 0.001 vs. VEH+PRE). The i.t. injection of this inhibitor alone (APO+VEH), in the absence of PRE, did not affect spinal pGluN1 expression in comparison to the VEH+VEH group. In addition, the effect of APO and the PKC inhibitor, chelerythrine (CHE) on PRE084-induced change in the pGluN1 expression was confirmed by Western blot analysis. As illustrated in Figs. 5C and D, APO (100 nmol, APO+PRE) or CHE (1 nmol, CHE+PRE) pretreatment significantly reduced PRE084-induced increase in PKC-dependent pGluN1 expression (Figs. 5C, D; *p < 0.05 vs. VEH+VEH, *p < 0.05, ***p < 0.001 vs. VEH+PRE).

Fig. 2. The Time Course of the Effects of Intrathecal Pretreatment with the nNOS Inhibitor (7-Nitroindazole, 7-NI, 200 nmol), the Nox Inhibitor (Apocynin, APO, 100 nmol) and the Peroxynitrite Scavenger (FeTPPS, 3 nmol), Respectively, on PRE084 (PRE, 3 nmol)-Induced Mechanical and Thermal Hypersensitivity

Paw withdrawal frequency (A, C; %) and response latency (B, D; s) were measured at 0, 30, 60, and 120 min after PRE injection using a von-Frey filament (0.16 g) and hot plate test (55±0.5°C), respectively. Intrathecal administration of 7-NI, APO, or FeTPPS was performed 10 min before PRE injection. n=5 mice/group. *p < 0.05, **p < 0.01, ***p < 0.001 vs. VEH+VEH; "p < 0.05, ""p < 0.01, """"p < 0.001 vs. VEH+PRE. PWF, paw withdrawal frequency.
DISCUSSION

It is well recognized that Sig-1Rs are predominantly localized to the endoplasmic reticulum in cells of the nervous system and play an important role in a variety of cellular signaling processes via modulation of intracellular Ca\(^{2+}\) levels.\(^{22,23}\)

Previous studies from our laboratory have shown that activation of spinal Sig-1Rs is critical for the inflammatory and neuropathic pain induced by formalin injection and chronic sciatic nerve injury.\(^{24,25}\)

These nociceptive effects of Sig-1Rs are associated with activation of Ca\(^{2+}\) dependent second messenger cascades via a phospholipase C-inositol triphosphate (PLC-IP\(_3\))-PKC signaling pathway leading to the potentiation of NMDA receptor activity via increases in PKC-dependent phosphorylation of the NMDA receptor GluN1 subunit (pGluN1).\(^{14,26}\)

In the present study, i.t. administration of the Sig-1R agonist, PRE084 was shown to induce both mechanical and thermal hypersensitivity in mice. I.t. pretreatment with either the nNOS inhibitor, 7-NI or the Nox inhibitor, apocynin attenuated this pain hypersensitivity. Since NO and superoxide (O\(_2^{-}\)) can combine to form the powerful and toxic oxidant, peroxynitrite anion (ONOO\(^{-}\)),\(^{27}\)

we examined whether peroxynitrite mediates the nociceptive effects induced by PRE084 administration. However, we found that i.t. administration of the peroxynitrite scavenger, FeTPPS had no effect on Sig-1R-induced pain hypersensitivity. These results indicate that spinal Sig-1R activation induces pain hypersensitivity via modulation of nNOS and Nox activation, while the convergence of NO and superoxide to produce peroxynitrite does not affect Sig-1R-induced nociception.

In the present study, Sig-1R activation was shown to significantly increase NO production in the lumbar spinal cord dorsal horn. It is well known that NO is synthesized in biological systems by three NOS enzymes (nNOS, iNOS, or eNOS).\(^{1}\)

Importantly, we demonstrate that only nNOS inhibition caused a significant reduction in the Sig-1R agonist-induced increase in spinal NO production, whereas iNOS and eNOS inhibition had no effect on this PRE084-induced increase in NO production. Furthermore, we recently demonstrated that activation of spinal nNOS is mechanistically associated with the PRE084-induced increase in paw pinch-evoked spinal cord Fos expression as well as in PKC-dependent pGluN1 expression.\(^{6}\)

Thus, we conclude that the Sig-1R-induced increase in NO production is most closely related to nNOS activation in the spinal cord. Since Sig-1Rs are abundant in astrocytes within the superficial dorsal horn of the spinal cord,\(^{25}\) it is likely that activation of Sig-1R may indirectly increase nNOS activity. In this regard, we have recently demonstrated that Sig-1R activation modulates the production of d-serine in spinal astrocytes, which contributes to the development of mechanical allodynia in a mouse model of neuropathic pain.\(^{28}\)

Since d-serine can modulate NMDA receptor activity as an endogenous ligand for the glycine site of this receptor,\(^{29}\) it is possible that d-serine released from astrocytes can regulate nNOS activity in nearby neurons. However, this indirect effect of Sig-1R activation on nNOS activity needs to be confirmed by further investigation.

Several reports have suggested that nNOS-derived NO stimulates Nox2 activation, which then links NMDA receptor activation with Nox2-dependent ROS production.\(^{9,30}\) These
findings raise the possibility of a relationship between nNOS and Nox2 activation that is induced by stimulation of spinal Sig-1Rs. Accordingly we investigated whether activation of spinal Sig-1Rs and consequent nNOS-derived NO is associated with Nox2 activation in the spinal cord leading to an increase in the production of ROS. An increase in the membrane fraction of the Nox2 subunit p47phox has been considered to represent an increase in the active form of the Nox2 enzyme. Based on this assumption, we assessed the expression of p47phox in the membrane fraction as a specific indicator of Nox2 activation. In addition, it has been shown that phosphorylation of nNOS (pnNOS) at Ser847 reduces nNOS activity by inhibiting Ca\(^{2+}/CaM\) binding, which is a critical step in nNOS activation. In this regard, an observed decrease in pnNOS possibly represents an increase in nNOS activity. In the present study, we found that pretreatment with the nNOS inhibitor, 7-NI reduces the PRE084-induced increase in Nox2 activity and ROS production in the superficial dorsal horn (SDH, laminae I–II) of lumbar spinal cord. However, administration of the Nox inhibitor, apocynin did not modify the PRE084-induced change in pnNOS expression. Since nociceptive primary afferent neurons synapse with second order neurons mainly in lamina I and II of spinal dorsal horn, these results suggest the possibility that Sig-1R-induced Nox2 activation in the SDH region plays an important role in modulating spinal nociceptive transmission from the periphery to the CNS as a downstream signaling component of the nNOS-NO signaling cascade.

A number of recent reports suggest several possible mechanisms by which an increase in NO induces Nox2 activation. Based on in vitro results using cortical neuronal cultures, Girouard et al. suggested that the effect of NO on ROS production induced by NMDA receptor activation requires soluble guanylyl cyclase (sGC), cGMP and protein kinase G (PKG) activation. PKG can activate the small GTPase Rac1 supporting the induction of functional active Nox enzyme assembly. These findings suggest that NO-sGC-PKG signaling cascades may have pro-oxidant effects in the CNS via modulation of Nox activity and concomitant ROS production, which could serve to modulate persistent pain. On the other hand, there are several reports suggesting that NO signaling can produce analgesia. Activation of the NO-cGMP pathway in the periphery causes antinociception via opening ATP-sensitive K\(^+\) channels with a consequent increase in the K\(^+\) current, resulting in nociceptor desensitization. In addition, i.t. administration of a cGMP analog has been shown to either inhibit or facilitate synaptic transmission of nociceptive stimuli in the spinal cord depending on the dose. This dual effect of NO may result from distinct intracellular signaling pathways, which are dependent on the experimental models used for pain.

Fig. 4. The Effect of I.t. Administration of the Nox Inhibitor, Apocynin (APO, 100nmol) on the PRE084 (PRE, 3nmol)-Induced Decrease in the Number of Phosphorylated nNOS (pnNOS, Ser847)-Immunoreactive (ir) Cells and Total NO Concentration in the Lumbar Spinal Cord Dorsal Horn

Representative photomicrographs (A) of lumbar dorsal horn sections and a bar graph (B) illustrating that the PRE084-induced decrease in the number of pnNOS-ir cells was not changed by pretreatment with APO. Black arrows indicate representative pnNOS-ir cells in 4A. n=5–7 mice/group. Scale bar=100µm. (C) Total NO concentration was measured indirectly as the concentration of its stable decomposition product nitrate in the spinal cord dorsal horns. n=6 mice/group. Intrathecal administration of APO was performed 10min before PRE injection and the lumbar dorsal horn was sampled 30min after PRE injection. *p<0.05, ***p<0.001 vs. VEH+VEH; n.s. vs. VEH+PRE. SDH, superficial dorsal horn; NP, nucleus proprius; NECK, neck of dorsal horn; n.s., non-significance.
evaluation, on the type and phase of the nociceptive process, and on the site of activation.1,36) These differences require further investigation to clarify the role of NO in the underlying pathophysiological mechanisms of pain.

There is now considerable evidence that spinal NMDA receptors play a critical role in the process of ‘central sensitization,’ an essential phenomenon in the development of chronic pain.37,38) Phosphorylation of the NMDA receptor GluN1 subunit at serine residues increases the excitability and synaptic efficacy of neurons in spinal pain pathways by reducing the Mg²⁺ block and by increasing the probability of channel openings.39) In the present study, i.t. administration of the Sig-1R agonist, PRE084 results in a significant increase in the number of PKC-dependent pGluN1-ir cells in the lumbar spinal cord dorsal horn. This increase is significantly reduced by the pretreatment with the Nox inhibitor, apocynin. These results suggest that Sig-1R-induced Nox2 activation and the accompanying ROS production can modulate PKC activity via both direct and indirect modulation of PKC activity.

In the present study, the differential distribution of pnNOS-ir cells, DHE staining (which represents ROS production), and pGluN1-ir cells in the spinal cord dorsal horn raises an important mechanistic question to consider. Since NO is a diffusible gas and readily permeates cell membranes, it can diffuse from its site of production to act on other adjacent cells leading to stimulation of ROS production in the spinal cord.1) While ROS production was increased in the SDH region (laminae I–II) of the spinal cord, most of the PKC-dependent pGluN1-ir cells modulated by ROS were detected in the deeper dorsal horn (laminae III–IV and V–VI). One explanation for this discrepancy might be suggested from the findings of Simone et al.
showing that capsaicin-induced C-fiber stimulation increases the responses not only from SDH neurons, but also from many deep dorsal horn neurons.\textsuperscript{3,40} It has also been demonstrated that many deep dorsal horn neurons express neurokinin-1 receptors and have dorsal dendrites that project to the superficial dorsal horn.\textsuperscript{47} Moreover, inhibitory interneurons in the dorsal horn can reduce the excitability of spinal projection neurons in the deeper layers and subsequently attenuate the inputs from nociceptive afferent fibers.\textsuperscript{49} This anatomical framework is further supported by studies suggesting that ROS can reduce spinal \(\gamma\)-aminobutyric acid (GABA) release and enhance responses of the spinal wide dynamic range neurons.\textsuperscript{49,50}

Thus, even though ROS is primarily produced in the SDH by Sig-1R-induced nNOS activation, it may affect NMDA receptors located on deeper dorsal horn cells that convey nociceptive information to higher levels of the central nervous system.

It is well known that the responses of primary sensory neurons to mechanical and thermal stimulation are different. There are several studies suggesting that depletion of capsaicin sensitive primary afferents using an analog of capsaicin, resiniferatoxin (RTX), suppressed thermal hyperalgesia, but not mechanical allodynia, in several neuropathic pain models.\textsuperscript{51,52} In addition, Roh et al. demonstrated that peripheral nerve injury increases the number of pGluN1Ir neurons in the spinal cord dorsal horn, and this increase is significantly attenuated in the SDH (laminae I–II) and NECK (laminae V–VI), but not the NP (laminae III–IV), regions of the dorsal horn in RTX-pretreated neuropathic rats.\textsuperscript{53} These studies suggest that the development of thermal hyperalgesia is related to an increase in pGluN1 expression in the SDH and NECK regions of the dorsal horn. In contrast, low-threshold mechanoreceptive and wide dynamic range neurons are mainly distributed in the NP and NECK regions, and these neurons are involved in the signal transmission of tactile information in normal animals.\textsuperscript{53} In this regard, it may be possible that PRE084-induced mechanical hypersensitivity is related to an increase in pGluN1 expression in the NP and NECK regions of the dorsal horn, and PRE084-induced thermal hypersensitivity is related to an increase in pGluN1 expression in the SDH and NECK regions of the dorsal horn. However, further investigations considering the pathophysiological and anatomical evidence are needed to clarify the mechanisms of mechanical and thermal hypersensitivity associated with a variety of acute and chronic pain conditions.

In conclusion, the present study demonstrates that nNOS-derived NO signaling modulated by spinal Sig-1R activation increases Nox2 activity and concomitant ROS production, which leads to a ROS-induced increase in PKC-dependent pGluN1 expression in the spinal cord dorsal horn and the development of pain hypersensitivity. These findings suggest that the downstream NO signaling cascade contributes to the increase in ROS production, which plays an important role in the development of spinal Sig-1R-mediated pain hypersensitivity. Clearly increased understanding of this interaction is critical to expanding our knowledge of the role played by NO in Sig-1R-dependent neuropathy.
