The majority of breast cancer deaths result from the progression of this disease to a metastatic phenotype. Rac1 and Cdc42 are Rho family members that together with their downstream effectors, Wiskott–Aldrich Syndrome protein-family verprolin-homologous protein 2 (WAVE2) and Arp2/3, play an important role in cytoskeletal reorganization and the formation of membrane protrusions that promote cancer cell migration and invasion. γ-Tocotrienol, is a natural isoform within the vitamin E family of compounds that inhibits breast cancer cell growth and progression by suppressing various signaling pathways involved in mitogenic signaling and metastatic progression. Studies were conducted to examine the effects of γ-tocotrienol on Rac1/WAVE2 signaling dependent migration and invasion in highly metastatic mouse +SA and human MDA-MB-231 mammary cancer cells. Exposure to γ-tocotrienol resulted in a dose-responsive decrease in Rac1/WAVE2 signaling as characterized by a suppression in the levels of Rac1/Cdc42, phospho-Rac1/Cdc42, WAVE2, Arp2, and Arp3 expression. Additional studies also demonstrated that similar treatment with γ-tocotrienol resulted in a significant reduction in tumor cell migration and invasion. Taken together, these findings indicate that γ-tocotrienol treatment effectively inhibits Rac1/WAVE2 signaling and reduces metastatic phenotypic expression in mammary cancer cells, suggesting that γ-tocotrienol may provide some benefit as a novel therapeutic approach in the treatment of metastatic breast cancer.

Key words γ-tocotrienol; breast cancer; Rac1; Wiskott–Aldrich Syndrome protein-family verprolin-homologous protein 2 (WAVE2); migration; invasion

Breast cancer is the most common form of cancer in women and is second only to lung cancer as a leading cause of cancer mortality in the United States. The vast majority of breast cancer deaths result from the development and progression of the metastatic form of this disease, that is characterized by cancer cells detaching from the primary tumor and spreading to distant sites in the body such as the bone, brain, surrounding lymph nodes, liver, and lungs. Breast cancer metastasis is a complex and multistep process that includes morphological changes, detachment from the basement membrane, increased mobility and invasion into surrounding tissues, intravasation, circulation, adhesion, extravasation, and growth at distant sites. Since patient prognosis for metastatic breast cancer is very poor, there is great interest in developing anti-invasion therapies to improve patient treatment and survival.

An initial step in the metastasis process involves epithelial-to-mesenchymal transition (EMT), where neoplastic epithelial cells lose their cellular polarity and acquire mesenchymal-like mobility that allows them to invade surrounding tissues. This amoeboid-like movement requires the formation of cellular protrusions that result from the conversion of monomeric globular actin (G-actin) to polymerized filamentous actin (F-actin).

The Rho family of small G-proteins are members within the Ras superfamily that play an important role in metastasis by enhancing tumor cell motility and invasion. Specifically, Rac1 and Cdc42 are Rho family members that act to modulate cytoskeletal reorganization by activating actin polymerization. Wiskott–Aldrich Syndrome protein-family verprolin-homologous protein 2 (WAVE2) and the Arp2/3 complex are downstream effectors of Rac1/Cdc42 that induce the formation of membrane protrusions and ruffles that are required for tumor cell movement. There are several members within the WAVE family of proteins, but WAVE2 has been shown to be the most important regulating actin polymerization, lamel-lopodia formation and mesenchymal-like mobility in various cancer cell types. Previous studies have demonstrated that γ-tocotrienol, a natural isoform within the vitamin E family of compounds, is a potent anticancer agent that inhibits cancer cell growth and metastasis by inhibiting mitogenic signaling and EMT. In the present study, experiments were conducted to examine the effects of γ-tocotrienol on Rac1/WAVE2 signaling and subsequent migration and invasion in the highly metastatic mouse +SA and human MDA-MB-231 mammary tumor cells in vitro.

MATERIALS AND METHODS

Reagents and Antibodies Chemicals and reagents were obtained from Sigma-Aldrich (St. Louis, MO, U.S.A.), unless stated otherwise. Purified γ-tocotrienol was generously provided by First Tech International Ltd. (Hong Kong). Antibody for actin was purchased from Santa Cruz biotechnology (Dallas, TX, U.S.A.), Goat anti-rabbit secondary antibody (Ab) was purchased from PerkinElmer, Inc. Biosciences (Boston, MA, U.S.A.). Cultrex® BME Cell Invasion Assay Kit was purchased from Trevigen (Gaithersburg, MD, U.S.A.).

Cell Lines and Culture Conditions The +SA cell is a highly malignant mammary epithelial cell line that was originally isolated from a mammary adenocarcinoma that had developed spontaneously in a BALB/c female mouse. The CL-S1 cell is an immortalized normal mouse mammary epithelial cell line that was derived from the hyperplastic

Regular Article
nodule isolated from a BALB/c mouse and do not form solid tumors when implanted back into syngeneic mice.\textsuperscript{30,33} +SA and CL-S1 cells were maintained in serum-free defined media consisting of Dulbecco’s modified Eagle’s medium: nutrient mixture F-12 (DMEM/F12) containing 5 mg/mL bovine serum albumin (BSA), 10\(\mu\)g/mL transferrin, 100U/mL soybean trypsin inhibitor, 0.1 mg/mL streptomycin, 10\(\mu\)g/mL epidermal growth factor (EGF), and 10\(\mu\)g/mL insulin. The human MDA-MB-231 malignant breast cancer cells and normal MCF-10A mammary epithelial cells were purchased from American Type Culture Collection (Manassas, VA, U.S.A.). MDA-MB-231 mammary cancer cells were cultured in RPMI-1640 supplemented with 10% fetal bovine serum and supplemented with 100 U/mL penicillin, 0.1 mg/mL streptomycin, and 10\(\mu\)g/mL insulin, whereas MCF-10A cells were maintained in DMEM/F12 supplemented with 5% horse serum, 0.5\(\mu\)g/mL hydrocortisone, 20 ng/mL EGF, 100 U/mL penicillin, 0.1 mg/mL streptomycin, and 10\(\mu\)g/mL insulin. All normal and malignant mammary epithelial cell lines were maintained at 37°C in a humidified incubator supplied with 95% air and 5% CO\textsubscript{2}. For use in experimentation, cells were isolated and collected for stock culture by first rinsing them in sterile Ca\textsuperscript{2+} and Mg\textsuperscript{2+}-free phosphate-buffered saline (PBS) and then incubating cells in 0.05% trypsin containing 0.025% ethylenediaminetetraacetic acid (EDTA) in PBS for 5 min at 37°C. Cells were then collected by centrifugation and then resuspended in medium and counted manually using a hemocytometer.

**Experimental Treatments** The highly lipophilic \(\gamma\)-tocotrienol was first dissolved in absolute ethanol and then added to sterile 10% BSA in water and incubated at 37°C overnight with gentle shaking as described previously.\textsuperscript{34,35} This stock \(\gamma\)-tocotrienol solution was then used to prepare different concentrations of treatment media.

**Measurement of Viable Cell Number** For cell growth studies, (+SA, CL-S1, MDA-MB-231 and MCF-10A) cells were seeded at a density of 1\times10^4 cells/well in 96-well culture plates (6 replicates/group). The following day, cells were divided into various treatment groups and exposed to 0–20\(\mu\)M \(\gamma\)-tocotrienol. Cells were fed fresh treatment media every other day for 4 d. For cytotoxicity studies, (+SA, MDA-MB-231, CL-S1, and MCF-10A) cells were seeded at a density of 1\times10^4 cells/well in 96-well culture plates (6 replicates/group), fed control media and allowed to growth for a 3-d period (approximately 70% confluent). Cells were then divided into various treatment groups and treated with 0–60\(\mu\)M \(\gamma\)-tocotrienol for an acute 24-h culture period. The next day, viable cell count was determined using 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) colorimetric assay as described previously.\textsuperscript{34,35} Briefly, cells were incubated at 37°C for 3 h in control media containing 0.5 mg/mL MTT. Afterwards, media was removed and MTT crystals dissolved in dimethyl sulfoxide (DMSO; 100\(\mu\)L/well), and optical density of each sample was measured at 570 nm on a microplate reader (SpectraCount, Packard BioScience Company, Meriden, CT, U.S.A.). The number of cells/well was calculated against a

Fig. 1. Growth Inhibitory Effects of \(\gamma\)-Tocotrienol on Highly Malignant +SA (A) and MDA-MB-231 (B), and Immortalized Normal CL-S1 (C) and MCF-10A (D) Mammary Epithelial Cells

All cells were initially plated at a density of 1\times10^4 cells/well (6 wells/group) in 96-well plates. Cells were allowed to attach for a 24 h period and then subjected to their specific treatments for a 4-d culture period. The MTT colorimetric assay was used to count viable cell number. Vertical bars indicate the mean cell number±S.E.M. in each treatment group. \*p<0.05 as compared with their respective vehicle-treated control group.
standard curve prepared by plating known cell densities at the start of experimentation.

**Western Blot Analysis** MDA-MB-231 and +SA cells were initially plated at $1 \times 10^5$ cells/100 mm culture plate. The next day, cells were fed their respective treatment media containing 0–6 $\mu$M $\gamma$-tocotrienol for a 4-d culture period. Afterwards, cells were washed with PBS, trypsin was used to isolate cells and lysates were collected for later assay.35) The Bio-Rad protein assay kit (Bio-Rad, Hercules, CA, U.S.A.) was used to determine protein concentration in each sample. Equal amounts were loaded into each well and then electrophoresis through sodium dodecyl sulfate (SDS)-polyacrylamide minigels was performed. Proteins from each gel were then transferred at 30 V for 12–16 h at 4°C onto a single polyvinylidene fluoride membrane (Dupont, Boston, MA, U.S.A.). Membranes were then washed and incubated with specific primary antibodies diluted 1:1000 to 1:5000 as described previously.35) Membranes were then washed and incubated with their respective horseradish-peroxide conjugated secondary antibodies diluted 1:5000.35) Specific protein bands were visualized by chemiluminescence (Pierce, Rockford, IL, U.S.A.). Images of Western blots were acquired using the Syngene Imaging System (Fredrick, MD, U.S.A.). Actin bands were used to ensure equal sample loading in each lane. Scanning densitometric analysis was performed with Kodak Molecular Imaging Software 4.5 (Carestream Health Inc., New Haven, CT, U.S.A.). Experiments were repeated a minimum of 3 times, and representative images are shown in the figures.

**Immunocytochemical Fluorescence Staining** MDA-MB-231 and +SA cells were initially plated at $2 \times 10^5$ cells/chamber in 8-chamber glass (BD Falcon, San Jose, CA, U.S.A.) and maintained in control media. The next day, media was removed, cells washed in PBS and then cells were exposed to their respective treatment media (0–4 $\mu$M $\gamma$-tocotrienol) for a 4-d culture period. Afterwards, cells were washed, fixed in 4% paraformaldehyde/PBS and then permeabilized with 0.2% Triton X-100/PBS as described previously.36) Fixed cells were then washed, blocked with 5% goat serum, and exposed to the primary Ab for WAVE2 (1:1000) at 4°C overnight.36) The following day, cells were washed and then incubation with Alexa Fluor 488 conjugated secondary Ab (1:5000).36) Slides were then washed and mounted with Vectashield medium containing 4′,6-diamidino-2-phenylindole (DAPI) (Vector Laboratories Inc., CA, U.S.A.). A LSM Pascal confocal microscope (Carl Zeiss Microimaging Inc, Thornwood, NY, U.S.A.) was then used to capture fluorescence images.

**Invasion Assay** Cancer cell invasion was assessed using the Cultrex® 96-well basement membrane extract (BME) cell invasion assay kit as described in the instructions (Trevigen Inc., Gaithersburg, MD, U.S.A.). Briefly, +SA and MDA-MB-231 cells were plated at a density of $1 \times 10^6$ cells/100 mm culture plate and maintained in their respective control media for a 3-d culture period (approximately 70% confluent). Afterwards, cells were washed in sterile PBS, given serum-free media and starved for a 24-h culture period. The next day cells were isolated with trypsin, washed, counted and

**Biol. Pharm. Bull.**

5 \times 10^4 \text{cells/well (5 wells/group)} was plated on the top invasion chamber of the 96-well plate provided in the kit in 50 µL of media containing 0 or 4 µM γ-tocotrienol. At the same time, 150 µL of that group’s respective control or treatment media was placed in the bottom chamber treatment of the plate. After a 24 h incubation period, the top chamber of cells in each treatment group was then washed, treated with the assay solution for 1 h and then samples were read at 485 nm excitation, 520 nm emission. Fluorescence intensity for each sample was then read against a standard curve to determine percent cell invasion as describe in the instructions provided in the kit.

**Migration Assay**

MDA-MB-231 and +SA cells were plated in 24-well plates (6 replicates/group) and returned to the incubator overnight to form a sub-confluent cell monolayer. Wounds were then made by making a scratch with a sterile 200-µL-micropipette tip. Media was then removed, cells washed, and then cells were fed their respective serum-free treatment media containing 0–4 µM γ-tocotrienol and 10 ng/mL EGF as a mitogen. After a 24 h incubation period, media was removed, washed in ice-cold PBS, fixed in −20°C methanol, and then stained with Giemsa reagent. Images were visualized using a phase-contrast microscopy (Nikon Eclipse TS100 inverted microscope, Nikon Instruments Inc., Melville, NY, U.S.A.).

**Statistical Analysis**

Differences among treatment groups was determined using one-way ANOVA followed by Dunnett’s t test. p < 0.05 was considered to be statistically significant as compared with their respective control groups.

**RESULTS**

**Growth Inhibitory Effects of γ-Tocotrienol on Normal and Neoplastic Mouse and Human Mammary Epithelial Cells**

After a 4-d treatment period, γ-tocotrienol induced a dose-responsive inhibition in growth of mouse (+SA) and human (MDA-MB-231) mammary tumors cells as compared to cells in their respective vehicle-treated control groups (Figs. 1A, B). However, treatment with higher doses of γ-tocotrienol had no effect on immortalized normal mouse (CL-S1) and human (MCF-10A) mammary epithelial cells (Figs. 1C, D). The IC_{50} dose for γ-tocotrienol was determined to be 4.3 and 4.4 µM for +SA and MDA-MB-231 mammary tumor cells, respectively.

**Acute Cytotoxic Effects of γ-Tocotrienol on Normal and Neoplastic Mouse and Human Mammary Epithelial Cells**

After an acute 24 h treatment exposure, γ-tocotrienol induced a dose-responsive reduction in viability of +SA and
MDA-MB-231 mammary tumors cells as compared to cells in their respective vehicle-treated control groups (Figs. 2A, B). Treatment with higher doses of γ-tocotrienol had little or no effect on viability of immortalized normal mouse (CL-S1) and human (MCF-10A) mammary epithelial cells (Figs. 2C, D). The LD_{50} dose for γ-tocotrienol was determined to be 14.7 and 28 μM for +SA and MDA-MB-231 mammary tumor cells, respectively. Based on the results obtained in the antiproliferative (Fig. 1) and cytotoxic (Fig. 2) studies, treatment doses between 0–6 μM γ-tocotrienol was selected for use in subsequent experiments because these doses inhibited cell growth, but were not cytotoxic to both +SA and MDA-MB-231 mammary tumor cells.

Effects of γ-Tocotrienol on Rac1/WAVE2 Signaling Protein Expression in Mammary Tumor Cells Western blot analysis shows that after a 4-d treatment period with 0–6 μM γ-tocotrienol, +SA and MDA-MB-231 mammary tumor cells displayed a dose-responsive decrease in Rac1/Cdc42, phospho-Rac1/Cdc42, WAVE2, Arp2, and Arp3, as compared with cells in their respective vehicle-treated control groups (Figs. 3A, B).
Scanning densitometric analysis of Western blots showed that treatment with 4–6 µM γ-tocotrienol significantly decreased Rac1/Cdc42, pRac1/Cdc42, WAVE2, Arp2, and Arp3 levels, as compared with cells in their respective vehicle-treated control groups (Figs. 3C, D).

Effects of γ-Tocotrienol on WAVE2 Immunofluorescent Staining in Mammary Tumor Cells +SA (Fig. 4A) and MDA-MB-231 (Fig. 4B) cells in their respective vehicle-treated control groups displayed a moderate level of positive WAVE2 immunofluorescence staining. Treatment with 4 µM γ-tocotrienol resulted in nearly a complete elimination of positive WAVE2 immunofluorescence staining (Figs. 4A, B). Image analysis of fluorescence photomicrographs showed that treatment with 4 µM tocotrienol resulted in a significant decrease in positive WAVE2 staining in both +SA (Fig. 4C) and MDA-MB-231 (Fig. 4D) mammary tumor cells, as compared to cells in their respective vehicle-treated control groups.

Effects of γ-Tocotrienol on Mammary Tumor Cell Invasion The Cultrex® BME cell invasion assay was used to determine the effects of γ-tocotrienol on mouse (+SA) and human (MDA-MB-231) breast cancer cell invasion. Results showed that +SA and MDA-MB-231 cells in the vehicle-treated control groups displayed nearly complete invasion into the BME, whereas treatment with 4 µM γ-tocotrienol caused an approximate 50% reduction in +SA and MDA-MB-231 cell invasion into the BME, as compared to cells in their respective vehicle-treated control groups (Fig. 5).
DISCUSSION

Results from these studies demonstrate that treatment with 4μM γ-tocotrienol induced a significant inhibition in growth of the highly metastatic mouse (+SA) and human (MDA-MB-231) mammary tumor cells. However, treatment with higher doses of γ-tocotrienol had little or no effect on the growth or viability of immortalized normal mouse (CL-S1) and human (MCF-10A) mammary epithelial cells, indicating that cancer cells display a selective sensitivity to the antiproliferative effects of γ-tocotrienol, as compared to normal, non-cancerous cells. The antiproliferative effects of γ-tocotrienol were associated with a significant reduction in Rac1/WAVE2 signaling as characterized by a suppression in the levels of Rac1/Cdc42, pRac1/Cdc42, WAVE2, Arp2, and Arp3 expression in mammary tumor cells. Additional studies showed that similar treatment with γ-tocotrienol resulted in a significant reduction in tumor cell migration and invasion. Taken together, these findings indicate that exposure to γ-tocotrienol effectively inhibits Rac1/WAVE2 signaling and these effects are associated with an attenuation in metastatic phenotype expression in the highly malignant breast cancer cells. A schematic representation of the inhibitory effects of γ-tocotrienol on Rac1/WAVE2 signaling and resulting reduction in metastatic activity is summarized in Fig. 7.

The anticancer effects of tocotrienols have previously been described in detail. A great deal of evidence indicates that the anticancer activity of γ-tocotrienol is mediated, at least in part, by its accumulation and disruption of lipid raft integrity and suppression of receptor activation and signaling. Specifically, studies have shown that breast cancer cells exposed to growth inhibiting doses of γ-tocotrienol display significant inhibition in HER2/ErbB2, HER3/ErbB3, HER4/ErbB4, and c-Met activation, and their downstream effectors including mitogen-activated protein kinase (MAPK), phosphatidylinositol 3-kinase (PI3K)/Akt, Stat, and nuclear factor-kappa B (NFκB). Furthermore, γ-tocotrienol suppression of c-Met receptor signaling was directly associated with a suppression in EMT, as evidence by an increased expression of epithelial markers such as E-cadherin, β-catenin, and cytokeratins 8/18 and corresponding decrease in the expression of vimentin, a mesenchymal marker.

It is now well established that Rac1/WAVE2 signaling plays an important role in promoting EMT and metastasis in a variety of cancer cell types. Studies have also shown that overexpression of Rac1 and/or Cdc42 is commonly observed in metastatic breast cancer and is associated with a poor patient prognosis. WAVE2 and Arp2/3 are the primary downstream effectors for Rac1/Cdc42, and stimulate actin polymerization, lamellipodia formation and elongation, and mesenchymal-like mobility and migration. Findings in the present study show that γ-tocotrienol treatment results in a significant and dose-responsive decrease in total and phospho-Rac1/Cdc42, and corresponding decrease in WAVE2, Arp2 and Arp3 levels in the highly metastatic +SA and MDA-MB-231 breast cancer cells. Immunofluorescence studies confirmed these findings and showed that similar treatment with γ-tocotrienol resulted in a large reduction in positive WAVE2 staining in these metastatic breast cancer cell lines.

Rac1/WAVE2 dependent actin polymerization is required for cytoskeletal mediated cellular protrusions, membrane ruffling and mobility. Results showed that γ-tocotrienol-induced inhibition of Rac1/WAVE2 signaling was associated with a suppression in invasion and mobility. Specifically, γ-tocotrienol treatment significantly inhibited the invasion of highly malignant +SA and MDA-MB-231 breast cancer cells through a basement membrane matrix. In addition, similar treatment with γ-tocotrienol significantly inhibited the mobility of these same cells as determined in the wound healing assay. These findings strongly suggest that γ-tocotrienol-induced inhibitory effects on Rac1/WAVE2 signaling is associated with a suppression in cytoskeletal changes that are related to cellular mobility and invasion in metastatic breast cancer cells.
Previous studies have investigated the role of WAVE proteins in actin polymerization, membrane protrusions and mobility in breast cancer cells. Analysis of the three WAVE proteins in actin polymerization, membrane protrusions and not in surrounding non-cancerous tissue. Other studies showed that Arp2 and WAVE2 are co-expressed in a high percentage of invasive ductal breast carcinomas, but not in surrounding non-cancerous tissue. Furthermore, cellular protrusions required the translocation of WAVE2 to the leading edge of the lamellipodia for Rac1 dependent migration and invasion of MDA-MB-231 breast cancer cells. Taken together, findings in the present study provide evidence to suggest that the inhibitory effects of γ-tocotrienol on malignant +SA and MDA-MB-231 breast cancer cell migration and invasion, appears to be mediated by a suppression in Rac1/WAVE2 signaling, and indicate that γ-tocotrienol may provide some benefit in the treatment of metastatic breast cancer.
