Inflammatory bowel disease (IBD) is a refractory illness with remarkably increasing incidence rate all over the world. However, no desirable treatment scheme is available. Therefore, research and development of new drugs for treating IBD are urgently needed. Histone deacetylase 6 (HDAC6) is considered to be a pro-inflammatory factor, thus the inhibitors specifically-targeting HDAC6 may find their way in IBD treatment. In this study, we evaluated the anti-inflammatory activity of a novel potent and selective HDAC6 inhibitor, LTB2, in dextran sulfate sodium (DSS)-induced colitis mouse model. It was found that LTB2 treatment significantly alleviated DSS-induced colitis in mice, as evidenced by body weight, colon length, histological examination, and the disease activity index (DAI) scores of rectal bleeding and diarrhea. More importantly, it showed a better protective effect on the DSS-induced colitis mice than the commonly used mesalazine in the clinic. Our results demonstrated that selective HDAC6 inhibitors may have a good prospect for IBD treatment.

Key words histone deacetylase 6 inhibitor; colitis; inflammatory bowel disease; anti-inflammatory activity

Crohn’s disease (CD) and ulcerative colitis (UC) are the two phenotypes of inflammatory bowel disease (IBD), of which the exact pathogenesis is still unclear.1 The commonly used medications for IBD treatment mainly contain anti-inflammatory drugs, corticosteroids, biologics and immunosuppressants. Unfortunately, most of these medicines can only attenuate the IBD symptoms, rather than completely cure the disease, and the concomitant adverse effects of these drugs also cannot be overlooked.2–5 With the increasing incidence rate and prevalence of IBD in most of the global areas, development of new effective and safe drugs is in great need.6–10

Recently, histone deacetylases (HDACs) are reported to have a close link to intestinal inflammation.11 HDACs contain 18 isoforms which are divided into four groups: class I (HDAC1, 2, 3, 8), class II (IIa, HDAC4, 5, 7, 9; IIb, HDAC6, 10), class III (SIRT1-7) and class IV (HDAC11).12 At present, some broad-spectrum HDAC inhibitors like vorinostat (SAHA) have proved their anti-inflammatory activities in dextran sulfate sodium (DSS)-induced colitis mouse model.13,14 However, adverse effects of these nonselective HDACi have been reported, mainly including diarrhea, nausea, vomiting and other intestinal symptoms, which undoubtedly limit the application of HDACi in IBD treatment.1 In fact, different HDACs may have various functions in IBD. For instance, HDAC2, 6, 9 are regarded as pro-inflammatory factors; while HDAC3 is the opposite, which is not expected to be inhibited in anti-IBD therapy.15–21 Furthermore, global deletion of HDAC1, HDAC3 or HDAC8 is associated to embryonic lethality.22–24 Hence, nonselective inhibition of HDACs may not be a good strategy for treating IBD according to these results.

HDAC6 is a unique isoform involving in various diseases including neurodegeneration, tumors and inflammation.25 HDAC6 inhibitors have been tested to be effective in several inflammatory models of mice.26–28 However, there are only a few researches about the selective HDAC6 inhibitors applied to IBD.18,29 Tubacin (the first selective HDAC6 inhibitor) was validated to protect mice from DSS-induced colitis through promoting the inhibitory activity of Foxp3+ T-regulatory cells (Tregs) via HDAC6 suppression in 2011.18 Although the poor pharmacokinetics of tubacin hindered its clinical development, the investigation did inspire us to exploit new selective HDAC6 inhibitors, with the hope of providing a new candidate drug for the treatment of IBD.

In previous medicinal chemistry work, we have designed and synthesized a series of novel potent HDAC6 inhibitors, which led to the discovery of LTB2 (the chemical structure will be disclosed later). LTB2 is a highly potent and selective HDAC6 inhibitor with an IC50 value of 3.9 nM, which is slightly better than the widely studied HDAC6 inhibitor tubastatin A. Here, we evaluated its therapeutic potential in DSS-induced colitis mice.

MATERIALS AND METHODS

Drugs and Chemicals Mesalazine (ME) was purchased from Energy Chemical of China. Tubastatin A (TA), a known selective HDAC6 inhibitor, was synthesized in our lab using the method of Butler et al.30 ME and TA were used as positive control drugs. LTB2 was designed and synthesized in our lab. The purity of TA and LTB2 is over 95% as quantitated by HPLC and their structural identity was confirmed by MS and 1H-NMR. DSS (MW=36000–50000) was purchased from MP Biomedicals (Solon, OH, U.S.A.).

Mice and Treatments All animal experimental protocols in this investigation were approved by the Administrative Committee of Experimental Animal Care and Use of the Second Military Medical University (SMMU), and consensus with National Institute of Health guidelines on the ethical use of animals. Six to eight week-old male C57BL/6J mice were obtained from Slac Laboratory Animal Co., Ltd. (Shanghai, China).

China) and raised in a house maintaining relatively constant temperature at 25±1°C and 55±5% humidity with a light/dark cycle of 12 h. All mice were accommodated for one week before the experiment. When the experiment came to the end, mice were sacrificed.

**DSS-Induced Colitis** DSS added to the drinking water (3%, w/v) was used to induce colitis. All mice were randomly divided into 5 groups (5 mice/group) with standard diet freely available for 7 d: 1) control group (water): free to drinking water; 2) colitis group (DSS): given 3% DSS in drinking water; 3) ME group (DSS+ME): given 3% DSS in drinking water and treated with ME (100 mg/kg, intragastrically (i.g.), quaque die (q.d.)); 4) TA group (DSS+TA): given 3% DSS in drinking water and treated with TA (10 mg/kg, intraperitoneally (i.p.), q.d.); 5) LTB2 group (DSS+LTB2): given 3% DSS in drinking water and treated with LTB2 (10 mg/kg, i.p., q.d.).

- a) Dextran sodium sulfate, dissolved in water.
- b) Weight of DSS/volume of water.
- c) Drink continuously during experiments. 1. Water: the mice were given drinking water only; 2. DSS: colitis group, the mice were given 3% DSS in drinking water; 3. DSS+ME: the mice were given 3% DSS in drinking water and were treated with ME (100 mg/kg); 4. DSS+TA: the mice were given 3% DSS in drinking water and were treated with TA (10 mg/kg); 5. DSS+LTB2: the mice were given 3% DSS in drinking water and were treated with LTB2 (10 mg/kg).

**Statistical Analysis** Data were displayed in the format of the mean±standard deviation (S.D.). Statistical analysis was operated on the platform of Prism 5.0 (GraphPad Software, San Diego, CA, U.S.A.), applying two-tailed Mann–Whitney test with 95% of confidence intervals to evaluate the significance of differences among the groups where necessary. p-Value below 0.05 means statistically significant.
RESULTS

LTB2 and TA Exerted Positive in Vivo Anti-inflammatory Activities as Selective HDAC6 Inhibitors The aqueous solution containing 3% DSS has been widely applied to induce mouse colitis, which imitates human IBD, particularly similar to UC. We tested the in vivo anti-colitis activity of LTB2 in DSS-induced mouse model, with ME and TA as positive compounds. Body weight, diarrhea and rectal bleeding of mice were recorded every day to evaluate the colitis, and results are presented in Fig. 1. The histological examination results of the colon tissue are shown in Fig. 2, which directly reflect the severity of colitis.

Body weights of the colitis mice were significantly decreased after DSS-treatment (Fig. 1A), and obvious rectal bleeding and diarrhea were examined for this group (Figs. 1C, D). At the same time, the colitis mice had shorter colon length, compared with the normal control group (water group). However, compared with the colitis group, mice receiving LTB2 lost remarkably less weight on the fifth, sixth and seventh day, and they had recovered rectal bleeding, diarrhea and longer colon lengths (Fig. 1). Histological analysis (Fig. 2) further confirmed that LTB2 could protect mice from severe inflammation. The colitis mice nearly lost all of the crypts and surface epithelia (Fig. 2B), whereas the LTB2-treated colitis group had recovered crypts and surface epithelia (Fig. 2E). Taken together, our compound LTB2 showed a sound efficacy against colitis, comparable or even better than ME and TA. These data indicated that LTB2 was promising for colitis treatment.

DISCUSSION

Pro-inflammatory function of HDAC6 has been validated. HDAC6 can regulate the reactive oxygen species (ROS)-mitogen-activated protein kinase (MAPK)-nuclear factor-kappaB (NF-κB)/activator protein-1 (AP-1) pathways, which leads to the expression of pro-inflammatory genes. In CD8 T cell-associated skin inflammation models, HDAC6 participates T-cell receptor signaling to modulate the proliferation and activation of CD 8 T cells during inflammatory response. Activation of HDAC6 induced by clostridium difficile toxin A causes hyper-deacetylation of tubulin and leads to depolymerization of microtubule in mouse intestine, which finally leads to severe inflammation. In addition, HDAC6 deficiency upregulates the acetylation level of microtubule, which results in enhanced p38 signaling and leads to the production of anti-inflammatory interleukin (IL)-10. HDAC6 suppression can inhibit the release of pro-inflammatory cytokines mainly including tumor necrosis factor (TNF)-α and IL-6. All these investigations
demonstrate that HDAC6 could be a promising target for anti-inflammation including IBD.

In this study, the anti-inflammatory activity of LTB2 (which was firstly designed and synthesized by our group) on DSS-induced colitis model of mice were evaluated. LTB2 was found to be efficacious at 10 mg/kg by intraperitoneal injection in C57BL/6J colitis mice. More importantly, LTB2 exhibited better efficacy than the commercial available medicine ME, and seemed to be superior to TA on suppression of colitis symptoms. The results suggest that selective HDAC6 inhibitors are indeed effective for DSS-induced colitis and our compound LTB2 is more potent than ME. More importantly, HDAC6 is considered to be dispensable for normal survival in animals even at 300 mg/kg. Therefore, selective HDAC6 inhibitors may provide a safer therapeutics for IBD.

In conclusion, this study suggested that selective HDAC6 inhibitors have a promising prospect in IBD treatment. Especially, the compound LTB2 discovered by our group can protect mice from DSS-induced colitis significantly, and it might be a potential therapeutic drug candidate for this disease.
