Psoriasis is a chronic inflammatory skin disease characterized by red, scaly and raised plaques. It affects approximately 2% of the population. The pathological alterations of psoriasis include profound acanthosis with elongation of epidermal rete ridges, increasing hyperkeratosis, loss of the granular layer, as well as parakeratosis. Although psoriasis is not life threatening, it can profoundly impact QOL, causing impairment skin to other major diseases including type 2 diabetes, myocardial infarction, and arthritis.

The molecular mechanisms underlying psoriasis are poorly understood. In addition to genetic susceptibility to psoriasis, infection, physical trauma, drugs as well as environmental factors have been recognized as triggers of psoriasis. Pathogenically, T-cell infiltration and associated elevated cytokine levels drive epidermal hyperplasia, resulting in the psoriatic phenotype. Focusing on pathogenic mechanisms, five therapeutic strategies have been developed, including inhibition of T cell activation, depletion of pathogenic T cells, blocking of leukocyte recruitment, inhibition of cytokines release, and immune regulation.

Sphingolipid sphingosine-1-phosphate (SIP) is a lysophospholipid regulator modulating a variety of immune cell trafficking via interactions with its cognate receptors, SIP₁₋₅. Activation of SIP signaling has recently emerged as a novel therapeutic avenue for psoriasis treatment. Here, we test a newly developed selective SIP₁ receptor modulator, Sy1930, in four different psoriasis animal models. Our data reveals that oral administration of Sy1930 can induce strong anti-proliferative and anti-inflammatory effects. Specifically, Sy1930 decreases the pathological thickening of back skin induced by sodium lauryl sulfate (SLS), inhibits the proliferation of basal cells in a vaginal epithelium model and increases the granular layer scales in a mouse tail assay. Moreover, Sy1930 can ameliorate the parakeratosis and acanthosis as well as improve granular layer composition and decrease the thickening of epidermis in a propranolol-induced guinea pig psoriasis model. Therefore, we demonstrate that Sy1930 is a promising candidate for psoriasis therapy in clinical.

Key words psoriasis; sphingolipid sphingosine-1-phosphate (SIP); SIP₁ modulator; Sy1930; animal model

MATERIALS AND METHODS

Reagents Sy1930 and FTY720 were synthesized according to previously described methods. Methotrexate (MTX) were obtained from Shanghai Pharma (Shanghai, China). For animal studies, Sy1930, MTX and FTY720 were dissolved in distilled water. Diethylstilbestrol was purchased from Melonepharma (Dalian, China). SLS was purchased from Sigma-Aldrich (St. Louis, MO, U.S.A.). Propranolol was obtained from Prosperity Galaxy Chemical (Hubei, China).

Animals Female KM mice specific-pathogen-free (SPF) were purchased from Vital River (Beijing, China). The mice were 6–8 weeks old and housed under standardized light in climate controlled conditions. Female guinea pigs were
purchased from National Institute of Food and Drug Center (Beijing, China). All animal experiments were carried out in accordance with the guidelines of the Committee on Animals of the Institute of Materia Medica, Chinese Academy of Medical Science & Peking Union Medical College (Permission Number: 00000189).

SLS-Induced Mouse Skin Irritation Model  KM mice were treated with 15% SLS solution daily on the shaved back skin for 7 consecutive days, for the negative control group, the KM mice were treated with distilled water. The SLS treated mice were grouped randomly and administrated orally with FTY720 (0.3 mg/kg) or different doses of Sy1930 once a day for 10 d. For vehicle groups, animals orally received distilled water only. All of the mice were sacrificed by cervical dislocation and back skin samples were collected for evaluation.

Diethylstilbestrol-Induced Mouse Psoriasis Model (Vaginal Epithelium Model) After female KM mice were injected intraperitoneally with diethylstilbestrol (0.2 mg) daily for 3 d, the mice were grouped randomly and treated orally with MTX (2.0 mg/kg, q.d.) or Sy1930 (1.0 mg/kg, q.d.) for 12 consecutive days. On the day 12, the mice were injected intraperitoneally with colchicin (2 mg/kg) to induce mitosis arrest. Six hours later the mice were sacrificed by cervical dislocation and vaginal samples were collected for histological evaluation. Skin samples were embedded in paraffin and 5 µm thick sections were prepared. The sections were then stained with hematoxylin/eosin. The mitotic cell numbers were determined among 300 randomly chosen basal cells. The mitotic index was calculated as (mitotic cell numbers/300)×100%.

Mouse Tail Assay The mouse tail assay was performed as previously described. Briefly KM mice were grouped and administrated orally with MTX (2.0 mg/kg), FTY720 (1.0 mg/kg) or Sy1930 (1.0, 3.0 mg/kg) daily for 12 d. Two hours after the last administration, the mice were sacrificed by cervical dislocation and tail samples were collected for histological examination. The presence of a modified granular layer was evaluated as previously described. In total 100 scales per animal were examined. The number of the modified granular layer scales (A) and the number of total scales (B) were counted for each mouse and the percentage of granular layer scale was calculated as follows: (A/B)×100%.

Propranolol-Induced Guinea Pig Psoriasis Model The propranolol-induced guinea pig psoriasis model was carried out as previously described. Briefly, guinea pigs were treated with 5% (m/v) propranolol ethanol solution containing azone and propanediol (1:3) on both ears twice a day to induce psoriasis. Three weeks later, guinea pigs were administrated orally with MTX (1.0 mg/kg) or Sy1930 (0.5, 1.0 mg/kg) daily for a period of 14 d, respectively. The animals were sacrificed by cervical dislocation and ear samples were collected for histological evaluation and scoring.

Histology Skin samples were embedded in paraffin and 5 µm thick sections were prepared. The sections were then stained with hematoxylin/eosin and evaluated in a double-blinded manner. The pathology score was assessed in respect to epidermal thickening, fibroplasia, inflammatory cell infiltration and vasodilation by a semi-quantitative examination (epidermal thickening: 0=no thickening, 1=slightly thickening of 5–7 layers, 2=moderate thickening of 8–10 layers, 3=severe thickening of more than 10 layers; fibroplasia: 0=no fibroplasia, 1=mild fibroplasia of less than 1/3 dermis thickness, 2=moderate fibroplasia of 1/3–2/3 dermis thickness, 3=severe fibroplasia of more than 2/3 dermis thickness; inflammatory cell infiltration: 0=no inflammatory cell infiltration, 1=mild inflammatory cell infiltration, 2=moderate inflammatory cell infiltration, 3=severe inflammatory cell infiltration with diffuse lesions; vasodilatation: 0=no vasodilatation in dermis, 1=mild vasodilatation in dermis, 2=moderate vasodilatation in dermis with limited area, 3=severe and diffuse vasodilatation in dermis). For the propranolol-induced guinea pig psoriasis model, the pathology score was evaluated in 3 different aspects including corneous layer, epidermis and dermis. The score index for corneous layer were Munro abscess, 1.5, hyperkeratosis, 0.5 and parakeratosis, 0.5–1.5. Epidermis was semi-quantitatively evaluated as lengthening of rete ridges, 0.5–1.5; lack of granular layer, 1; acanthosis, 1. The scores for dermis were determined as inflammatory cell infiltration, 0.5–1.5; papillary papillae congestion, 1; thinning above papillae, 1.

Statistical Analysis Unless otherwise specified, data are presented as the mean±standard error of the mean (S.E.M.). The statistical tests used and p values are indicated in each figure legend. Normally distributed data was statistically analyzed using unpaired two-tailed t-test for single comparisons, and two-way ANOVA for multiple comparisons. ANOVA analyses were followed by Bonferroni’s post hoc tests. p<0.05 was considered to indicate statistical significance. Numbers of mice per group used in each experiment are annotated in the corresponding figure legends as n. Statistical analysis was performed using Student’s t-test by Graphpad Prism 7.

RESULTS

SLS-Induced Mouse Skin Irritation Model To explore the potential effect of Sy1930 on skin inflammation, we firstly employed an SLS-induced mouse skin irritation model which

![Fig. 1. Sy1930 Inhibits SLS-Induced Mouse Skin Irritation](image-url)
could mimic the early skin symptom of psoriasis. Topical application of SLS to the shaved back of KM mice lead to inflammation characterized by a dramatic increase in the thickness of the skin. Our data indicated that oral administration of the positive control, FTY720, could decrease the thickening. Importantly, Syl930 also significantly attenuated the thickness of back skin induced by SLS in a dose-dependent manner (Fig. 1, Table 1), strongly supporting that Syl930 could inhibit the skin inflammation induced by SLS.

**Vaginal Epithelium Model** As diethylstilbestrol has been reported to induce mitotic drive of basal cell vaginal epithelium in female mice, it has been widely used as an indirect method to evaluate therapeutic potential for psoriasis. As shown in Fig. 2, administration of Syl930 at the dose of 1.0 mg/kg could significantly reduce the mitotic index of basal cells compared to vehicle group, and more efficient than the positive control, MTX at the dose of 2 mg/kg, which is a widely used immunosuppressant agent in the treatment of autoimmune diseases. Furthermore, Syl930 did not affect body weight during the treatment, while MTX decreased the body weight significantly (Table 2), thus highlighting that Syl930 could induce less toxicity.

**Mouse Tail Assay** Psoriatic skin exhibits pathological changes including marked hyperkeratosis and loss of the granular layer. The mouse tail test was a useful assay for studying dermatological therapeutics that influence orthokeratosis and granular layer. Thus, we applied this assay to evaluate the effect of Syl930. The number of granular layer scales was used to investigate the increase of orthokeratosis directly. As shown in Fig. 3, Syl930 at 3 mg/kg could increase the granular layer scales compared to control group while FTY720 had no impact on orthokeratosis induction. Of note, as a positive control, MTX at 2 mg/kg significantly induced orthokeratotic cell differentiation in the epidermal scales, which have been proved in rat tail model.

**Propranolol-Induced Guinea Pig Psoriasis Model** Finally, we used propranolol-induced guinea pig psoriasis model to assess the effect of Syl930 on psoriasis in an additional relevant model organism. The body weights showed in Table 3. Histological examination revealed an increase of parakeratosis, acanthosis, diminished granular layer and elongation of rete ridges, as well as dilated capillaries in propranolol-treated ears. Interestingly, Syl930 at the dose of 1.0 mg/kg reduced the parakeratosis and acanthosis, increased the granular layer, and decreased the thickening of epidermis (Figs. 4A–D). Similar results were observed in the positive control MTX treated group. Pathological scores revealed that Syl930 at the dose of 1.0 mg/kg could significantly improve the inflammatory parameters (Fig. 4E).

**DISCUSSION**

The molecular mechanisms underlying psoriasis remain
unclear. T cell infiltration and associated elevated cytokines level are considered important pathogenic triggers which initiate keratinocyte cell growth. Inhibition of cytokine release and their downstream signaling pathways, blocking of T cell infiltration, and immune regulation are major strategies for psoriasis treatment.\textsuperscript{3,4} For example, targeting interleukin (IL)-17 and its receptor show promising therapeutic effects for psoriasis treatment.\textsuperscript{20,21} JAK3 inhibitor also achieved good efficacy in phase III clinical trials. Considering the role of S1P in lymphocyte trafficking, it is conceivable that activation of S1P signaling could decrease the infiltrated T cell and thus represent another potential strategy for the treatment of psoriasis.

So far, fingolimod is the first and only approved S1P\textsubscript{1} modulator without S1P\textsubscript{3} selectivity.\textsuperscript{12} The next generation S1P\textsubscript{1} modulators with S1P\textsubscript{3} selectivity, such as siponimod, ponesimod, and oxanimod, are under clinical development for treatment of autoimmune diseases including multiple sclerosis, psoriasis, and ulcerative colitis.\textsuperscript{22} It has been reported that ponesimod treatment in patients with chronic plaque psoriasis achieved significant clinical benefits in a phase II study.\textsuperscript{23} Syl930, as a novel selective S1P\textsubscript{1} modulator, is now in phase I trial in China indicated for rheumatoid arthritis. Despite the effects of Syl930 on encephalomyelitis and rheumatoid arthritis have been tested in animal models, the effect of Syl930 on psoriasis is still unknown.

To explore the potential efficacy of Syl930 on psoriasis treatment, four animal models had been investigated. Considering psoriasis is in essence a skin disease, we firstly used SLS to induce skin irritation in mice. Both Syl930 and MTX diminished the irritation reaction characterized by thickening of the skin. The results indicated that this model is suitable for evaluating S1P\textsubscript{1} modulators and that Syl930 may have potential therapeutic effects on psoriasis. Encouraged by the results of the SLS experiment, we explored three classic psoriasis animal models to assess the effect of Syl930.

Fig. 3. Syl930 Increases Orthokeratosis in Mouse Tail Assay

KM mice were grouped and administrated orally with MTX (2.0 mg/kg), FTY720 (1.0 mg/kg) or Syl930 (1.0, 3.0 mg/kg) daily for 12 d. Tail samples were collected for evaluation. n=7 for each group. Data are indicated as mean±S.E.M. Compared to vehicle group, **p<0.01.

Fig. 4. Syl930 Ameliorates Propranolol-Induced Guinea Pig Psoriasis Model

Guinea pigs were treated with 5% (m/v) propranolol solution on both ears twice a day to induce psoriasis. The animals were orally administrated with MTX (1.0 mg/kg) or Syl930 (0.5, 1.0 mg/kg) daily for a total of 14 d. Ear samples were collected for histological evaluation. n=5 for each group. HE staining (100×) (A) Vehicle, (B) MTX, (C) Syl930 (0.5 mg/kg), (D) Syl930 (1.0 mg/kg). (E) Histological scoring results of different groups. Data are indicated as mean±S.E.M. Compared to vehicle group, *p<0.05, **p<0.01.
inhibits the proliferation of basal cells of vaginal epithelium and increases the orthokeratosis, which further highlights its potential use in psoriasis therapy. Finally, we used the established propranolol-induced guinea pig model to assess the anti-psoriasis effect of Sy930. As expected, it ameliorates the pathological damage of the skin in a dose-dependent manner. As the first-line therapeutic drug for psoriasis, MTX undoubtedly displays good effects. However, since MTX is an immunosuppressive drug, we observed severe the body weights reduction in the MTX treated group compared to control group, while it was not observed in the Sy930 group. Taken together, these results show that Sy930 is an eligible immunomodulator for psoriasis with a good safety profile.

Due to the differences in pathogenesis of psoriasis between human patients and rodents, these models might not reflect the physiological characteristics of psoriasis in patients and additional animal models should be applied and investigated. In the future, we will employ other animal models such as the imiquimod-induced mouse model and severe combined immunodeficient mouse models to further explore Sy930’s function. Taken together, based on the analysis with different animal model, we propose that oral administration of Syl930 exhibit potential therapeutic effects in these animal models. These results will be useful to evaluate preclinical effect of the SIP1 selective modulator and predict its efficacy clinically.
