Received December 16, 2018; accepted January 16, 2019

Signal transducer and activator of transcription 3 (STAT3) is a latent transcription factor that contributes to tumor cell growth and survival and is often constitutively active in several types of cancers, which makes it an attractive target for cancer therapy. We identified 5,5'-[(pentane-1,5-diyl)bis(2-methyl-1,4-benzoquinone)] (BPMB) as a new STAT3 inhibitor. BPMB inhibited the transcriptional activities of STAT3, despite its inability to reduce the phosphorylation and nuclear translocation of STAT3. BPMB selectively inhibited the proliferation of human breast cancer cell lines with constitutively activated STAT3. Furthermore, a gel retardation pattern was obtained by immunoblotting only when those STAT3-activated cell lines were treated with BPMB. The shifted bands could be immunoblotted with anti-STAT3 antibody but not with anti-STAT1/STAT5 antibody, and were stable under reducing conditions. The purified recombinant STAT3 protein treated with BPMB afforded a similar band shift pattern. Matrix-assisted laser desorption/ionization-mass spectrometry analysis of the component comprising the main shifted band suggested that the complex is a STAT3 homodimer crosslinked by BPMB through a Michael addition with Cys550 in the linker domain. Alanine replacement at this position resulted in reduction of the STAT3 domain conformation in the gel retardation assay. Thus, our results suggest that BPMB inhibits the proliferation of STAT3-activated cell lines, presumably through acylation of the linker domain and subsequent induction of the inactive STAT3 complexes.

**Key words** signal transducer and activator of transcription 3 (STAT3); inhibitor; cysteine; cancer

INTRODUCTION

Signal transducers and activators of transcription (STATs) are cytoplasmic transcription factors that relay signals from growth factors and cytokines in the cytoplasm to the nucleus. The STAT family comprises seven members: STAT1–STAT4, STAT5a, and STAT5b. Overexpression and/or constitutive activation of STAT3, in particular, have been detected in many types of hematopoietic and solid tumors, such as leukemia, and breast and prostate cancer.1–5 The STAT3 signaling pathway involves the activation of receptor tyrosine kinases, such as epidermal growth factor receptor and platelet-derived growth factor receptors, and Janus kinases (JAKs). Following phosphorylation of the conserved Tyr705 residue in STAT3 (e.g., PYXXQ in the gp130 receptor for STAT3 binding),6 two STAT3 monomers dimerize through a reciprocal interaction between p-Tyr705 and the Src homology 2 (SH2) domains. This results in the translocation of activated STAT3 dimers into the nucleus, where they regulate gene expression by binding to specific DNA sequences.7–10 The mode of constitutive activation of STAT3 through posttranslational modifications (e.g., tyrosine and serine phosphorylation, lysine acetylation,11,12 and redox regulation13,14) may vary in different types of cancers.

STAT3 plays a role in various biological functions, including cell proliferation, cell survival, apoptosis, and inflammation.15–17 The transcription of a number of genes involved in cell cycle progression, such as cyclin D1 and c-myc, as well as genes involved in angiogenesis (e.g., vascular endothelial growth factor) and anti-apoptosis (e.g., survivin, Bcl-2, and Bcl-xl) are activated by STAT3. It has been reported that STAT3 signaling restrains natural tumor immune surveillance and the inhibition of hematopoietic STAT3 in tumor-bearing hosts elicits multicomponent therapeutic antitumor immunity.18–20 It was also determined that in normal cells, blocking STAT3 is neither harmful nor toxic to the cells.21 The onco- genic functions of STAT3 and the therapeutic potential of its inhibition make the targeting of STAT3 an intriguing strategy in cancer treatment.

Several strategies have been examined to inhibit STAT3 activation, such as targeting the activating JAK2 kinase. Ruxolitinib22 and tofacitinib23 suppress the upper reaches of STAT signaling and induce apoptosis in tumor cells.24 However, JAK inhibitors target the ATP binding site, which is highly conserved across the known human protein kinases; thus, they are not STAT3-selective inhibitors. Therefore, there has been recent interest in STAT3-SH2 domain inhibitors and STAT3 DNA-binding inhibitors. Stattic and S3I-201 are STAT3-SH2 domain inhibitors designed to suppress the interaction between the SH2 domain and p-Tyr705.25,26 Galaliellalactone and inS3-54 target the DNA binding domain of STAT3, thereby disrupting STAT3-DNA interactions.27,28 We previously identified STAT3 direct inhibitors, namely, 2-chloro-1,4-naphthalenedione analogue,29 5,15-diphenylporphyrin,30 and STX-0119.31 However, only a limited number of STAT3-SH2 domain inhibitors and STAT3 DNA-binding inhibitors have reached pre-clinical and clinical trials. Several of these STAT3 inhibitors (e.g., stattic, galaliellalactone, and S3I-201) were re-

© 2019 The Pharmaceutical Society of Japan
ported to be irreversible cysteine binders. Consequently, further development of irreversible STAT3 inhibitors and determination of the detailed mode of action are important for the identification of new STAT3 inhibitors.

In this study, we identified 5,5′-(pentane-1,5′-diyl)bis-(2-methyl-1,4-benzoquinone) (BPMB) as a new STAT3 inhibitor. BPMB was previously synthesized by Hung et al. as an intermediate of N,N′-dicyanoquinodimine (DCNQI) copper salt analogues that exhibit metallic conductivity. However, to date, there has been no report of the biological activity of BPMB. We demonstrate here that BPMB inhibits the prolifer-ation of STAT3-activated cells and abrogates the STAT3 function presumably by the induction of stable STAT3 complexes including a homodimer through a bifunctional intermolecular covalent reaction with Cys550 in the linker domain.

MATERIALS AND METHODS

Reagents BPMB was purchased from Maybridge (U.K.). JAK inhibitor I was purchased from Sigma-Aldrich (U.S.A.). Anti-STAT3, anti-STAT1, anti-STAT5, anti-phospho STAT3 (Tyr705), and anti-phospho STAT3 (Ser727) antibodies were obtained from Cell Signaling Technology (U.S.A.). Anti-STAT3, anti-STAT1, anti-STAT5, anti-phospho STAT3 (Tyr705), and anti-phospho STAT3 (Ser727) antibodies were purchased from the American Type Culture Collection (ATCC). Anti-glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was purchased from Wako (Japan) and Sigma-Aldrich, respectively. Escherichia coli, strain BL-21 (DE3) pLySs, was purchased from Life Technologies Corporation (U.S.A.). pBluescript II KS (+) was bought from Stratagene (U.S.A.) and pET-28a (+) was obtained from Novogene (China). PhosphoSafe Extraction Reagent was purchased from Merck (U.S.A.), and Protein G Plus/Protein A Agarose Suspension was obtained from EMD Millipore (U.S.A.). The other reagents were purchased from Nacalai Tesque (Japan).

Cell Lines and Culture The STAT3 and STAT1 reporter HeLa stable cell lines for the luciferase reporter gene assay were purchased from Signosis (U.S.A.) (product No. SL-0003 and SL-0004, respectively). Cells were grown in Dulbecco's Modified Eagle's Medium (DMEM) in addition to 10% (v/v) fetal bovine serum (FBS), 200 µM penicillin, 20 µg/mL streptomycin, and 100 µg/mL hygromycin B at 37°C in a humidified atmosphere with 5% CO2. HeLa cells (cervical carcinoma) were obtained from RIKEN BRC (Japan). The cells were maintained in DMEM supplemented with 10% (v/v) FBS, 200 µM penicillin, and 20 µg/mL streptomycin at 37°C in a humidified atmosphere with 5% CO2. HeLa cells (cervical carcinoma) were obtained from RIKEN BRC (Japan). The cells were maintained in DMEM supplemented with 10% (v/v) FBS, 200 µM penicillin, and 20 µg/mL streptomycin at 37°C in a humidified atmosphere with 5% CO2. HeLa cells (cervical carcinoma) were obtained from RIKEN BRC (Japan). The cells were maintained in DMEM supplemented with 10% (v/v) FBS, 200 µM penicillin, and 20 µg/mL streptomycin at 37°C in a humidified atmosphere with 5% CO2.

Luciferase Reporter Gene Assay For the STAT3/STAT1-dependent reporter assay, the cells (2 × 104 cells/well) were seeded into white 96-well plates (Corning, U.S.A.) and incubated overnight at 37°C in 5% CO2. The cells were treated with vehicle or test compounds for 1 h. The cells were then stimulated with 10 ng/mL OSM (STAT3) or 6 ng/mL IFN-γ (STAT1) for 4 h. The medium was aspirated off and SteadyGlo (Promega) was added to the cells. The plate was then placed on a shaker 6 for 10 min. Luminescence was detected using an ARVO Light plate reader (PerkinElmer, Inc., U.S.A.). The relative signal intensity was calculated in each well as the ratio for the mean signal of the vehicle.

Western Blot Analysis The samples were subjected to...
sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and stained with Imperial Protein Stain (Thermo Fisher Scientific, U.S.A.). For Western blotting, the proteins were transferred onto a polyvinylidene fluoride membrane. The membranes were incubated with blocking buffer (5% (w/v) skim milk in Tris-buffered saline (pH 7.4) and 0.1% (v/v) Tween 20) overnight at 4°C. They were then incubated with primary antibody diluted in blocking buffer overnight at 4°C. Thereafter, they were incubated with HRP-conjugated secondary antibodies diluted in blocking buffer for 1 h at room temperature. Immunoblots were developed by using a chemiluminescent substrate and detected using a LAS-3000 imager (GE Healthcare).

**Nuclear Translocation Assay** The Cellomics STAT3 Activation Kit (Thermo Scientific) was used for the nuclear translocation assay. HeLa cells (1 × 10^5 cells/well) were incubated in a 96-well microplate for 24 h. The cells were pretreated with vehicle or test compounds for 1 h, and 30 ng/mL OSM was applied and the mixture was incubated for 10 min. The subsequent procedures were performed according to the manufacturer’s instructions. In brief, fixation solution was applied and incubation for 10 min. The cells were incubated with permeabilization buffer for 15 min and were incubated with the primary antibody for 1 h, followed by secondary antibody for 1 h and then incubated with 10% Vectorshield (H-1000). The cells were scanned with an ArrayScan VTI reader (Thermo Scientific), and analyzed with the Cytoplasm to Nucleus Translocation Application. The mean fluorescent values in the nuclei were calculated. The signals for vehicle treatment and no treatment (without oncostatin M) were represented as 100 and 0%, respectively, and the relative signal intensity was also calculated.

**Gel Retardation Assay** Whole-cell lysates prepared from OSM-stimulated cells or the purified rhSTAT3 protein were incubated with vehicle or BPMB for 1 h at 4°C. The samples were subjected to SDS-PAGE and subsequent blotting with streptavidin–HRP conjugate.

**Immunoprecipitation** Cells were treated vehicle or BPMB for 1 h and lysed in PhosphoSafe extraction reagent. The lysates were precleared with a mixture of Protein G Plus/Protein A agarose suspension for 20 min at 4°C. Bead pellets were discarded by centrifugation at 15000 rpm for 5 min and the supernatant was retained for immunoprecipitation. The lysates were immunoprecipitated with anti-STAT3 antibody for 4 h at 4°C on a rotator. The immunocomplexes were captured by the addition of a Protein G Plus/Protein A Agarose Suspension slurry overnight at 4°C. Samples were rinsed three times with lysis buffer and equal amounts of protein were subjected to SDS-PAGE and subsequent Western blotting.

**Mass Spectrometry Analysis of the Adduct of BPMB with rhSTAT3** Samples were subjected to SDS-PAGE and stained with Imperial Protein Stain. The component of the main shifted band was decolored with reagents containing 50 mM ammonium bicine and 50% (v/v) acetonitrile and then reduced in the gel with 100 mM DTT in 80 mM ammonium bicine for 30 min at 56°C. The gel pieces were incubated with 100 mM iodoacetamide in 80 mM ammonium bicine for 45 min with shaking at room temperature and then digested by 0.01 μg/μL trypsin for 16 h at 37°C. Digestion was stopped by the addition of 0.1% (v/v) trifluoroacetic acid in 50% (v/v) acetonitrile. Tryptic peptides were extracted and 1 μL was mixed with an equal volume of 3 g/L 5-dihydroxybenzoic acid and 0.1% (v/v) trifluoroacetic acid in 30% (v/v) acetonitrile as a matrix, loaded onto the target plate, and air-dried. The samples were analyzed by ultraflex Xtreme (Bruker Daltonics, U.S.A.) in the positive mode. The data were processed by Mascot Distiller searching the NCBI RefSeq human database.

**WST-8 Assay** Cells were plated in a 96-well tissue culture plate and incubated for 24 h. Cells were treated with vehicle or BPMB (0.1–3 μM) for 72 h. After incubation, WST-8 solution (Dojindo Molecular Technologies, U.S.A.) was added to each well and incubated at 37°C for 4 h, and the absorbance was read at 450 nm.

**Statistical Analysis** All experiments were performed in triplicate. In the nuclear translocation assay, the statistical significance was calculated by Student’s t-test with *p < 0.05 and **p < 0.01 versus vehicle treatment. In the luciferase reporter gene assay, statistical significance was calculated by Student’s t-test with *p < 0.05 and **p < 0.01 versus luc-STAT3. In the WST-8 assay, statistical significance was calculated by one-way ANOVA followed by Tukey’s multiple comparisons test.

**RESULTS**

BPMB Inhibited Transcriptional Activation of STAT3 without Affecting Its Phosphorylation Status and Nuclear Translocation

In our screening campaign for STAT3 inhibitors, we identified BPMB as a hit compound by its ability to inhibit STAT3-transcriptional activity (Fig. 1a). As shown in Fig. 1b, BPMB inhibited STAT3-dependent transcriptional activity (half maximal inhibitory concentration (IC_{50}) = 3.57 μM) but not STAT1-dependent transcriptional activity (IC_{50} > 10 μM). To verify that BPMB inhibited STAT3 activation, we examined its effect on the phosphorylation of STAT3 in OSM-stimulated HeLa cells (Figs. 1c, d). Phosphorylation of STAT3 was observed in HeLa cells stimulated with OSM and treatment with increasing concentrations of BPMB rarely affected the phosphorylation status of either Tyr705 or Ser727.

We investigated the effect of BPMB on STAT3 nuclear translocation by immunostaining. As shown in Figs. 1e and f, nuclear translocation of STAT3 was observed within 10 min in HeLa cells stimulated with OSM. The addition of BPMB up to 60 μM resulted in no significant reduction in nuclear STAT3. These results suggest that BPMB may directly inhibit STAT3 without affecting the upstream regulators or nuclear import factors.

Inhibition of Proliferation and Induction of STAT3 Complexes by BPMB in STAT3-Activated Cancer Cells

We examined whether BPMB could inhibit proliferation in human breast cancer cells with constitutively activated STAT3. Constitutive phosphorylation of STAT3 was observed in MDA-MB-231 and MDA-MB-453 cells, but not in MDA-MB-453 or MCF7 cells (Fig. 2b). The cells were treated with 0.1–3 μM BPMB for 72 h and assessed using the WST-8 cell proliferation assay. As shown in Fig. 2a and Supplementary Table 1, BPMB significantly suppressed the proliferation of MDA-MB-231 and MDA-MB-468 cells in a dose-dependent manner, but did not affect MDA-MB-453 or MCF7 cells. Those results demonstrate that BPMB selectively inhibits the proliferation of cell lines with constitutively activated STAT3.
Fig. 1. Identification of BPMB, Which Inhibited STAT3 Transcriptional Activity without Affecting Its Phosphorylation Status and Nuclear Translocation in Cells

(a) Structure of BPMB. (b) The STAT3 (●) and STAT1 (□) stable cell lines were pretreated with or without BPMB for 1 h, and then stimulated with 10 ng/mL OSM or 6 ng/mL IFN-γ for 4 h, followed by detection of STAT3 or STAT1-dependent luciferase activity. The error bars represent the standard deviation from the mean (*p < 0.05 and **p < 0.01 versus luc-STAT3 using the Student’s t-test). (c) Effect of BPMB on the phosphorylation of Tyr705 and Ser727 in STAT3. HeLa cells were pretreated with the indicated concentrations of BPMB for 4 h, and then were stimulated with OSM for 30 min. The cells were lysed for Western blotting analysis. (d) HeLa cells were treated with or without BPMB (10 µM) for the indicated periods (1–6 h), and then were stimulated with OSM for 30 min. (e) Fluorescence images of STAT3 proteins in the nuclei of HeLa cells. HeLa cells were pretreated with or without BPMB, and then either treated with OSM or left untreated. The cell nuclei were stained with Hoechst 33342 and the STAT3 proteins were visualized with an anti-STAT3 antibody. The merged image shows the fusion of blue (nuclei) and green (STAT3) fluorescence. Cells untreated with either OSM or BPMB are shown as “− OSM.” Cells pretreated with 0.1% DMSO, and then treated with OSM are shown as “OSM + vehicle.” (f) The mean fluorescence values of STAT3 in the nuclei were calculated. The fluorescence signals obtained from cells treated with OSM but not the test compounds (“vehicle”) and “− OSM” were used for the 100 and 0% signals, respectively. The relative signal intensity was calculated in each well. Each point represents the mean from three replicates, and the error bars represent the standard deviation from the mean (*p < 0.05 and **p < 0.01 versus vehicle using the Student’s t-test). JAK inhibitor I was used as a positive control. (Color figure can be accessed in the online version.)
STAT3 antibody were detected with anti-STAT3, or anti-P-STAT3 (Tyr705) immunoblotting. The STAT3-containing large complexes that precipitated with anti-STAT3 antibody. They are, therefore, SDS-resistant protein complexes from cell lysates of MDA-MB-231 and MDA-MB-468 cells treated with BPMB for 1 h. The STAT3-containing large complexes that precipitated with anti-STAT3 antibody. They are, therefore, SDS-resistant protein complexes that precipitated with anti-STAT3 antibody from HeLa cell lysates. The immunoprecipitates from BPMB-treated cell lysates were immunoblotted with anti-STAT3, anti-STAT1, or anti-STAT5 antibodies. A similar gel retardation pattern was only detectable by the anti-STAT3 antibody in HeLa cells stimulated with OSM (Fig. 3a), suggesting that BPMB preferentially interacted with Tyr-phosphorylated STAT3 in cells and the large complexes could be STAT3 homooligomers or complexes with other STAT3 binding partners.

A previous study reported that H₂O₂ generates STAT3 oligomers. We attempted to understand the differences between STAT3 complexes formed by exposure to H₂O₂ or BPMB. To this end, the STAT3 complexes induced by H₂O₂ or BPMB were pre-treated with a reducing agent in lysates from OSM-stimulated cells before PAGE-separation and immunoblotting. The gel retardation pattern by exposure to H₂O₂ and BPMB was also detected in in vitro experiments. Although the band corresponding to the STAT3 oligomers formed by H₂O₂ collapsed, the bands corresponding to STAT3 complexes formed by BPMB were not labile in the presence of 100 mM DTT (Fig. 3b). Additionally, the mobilities of the STAT3 complexes within the gel differed between those formed by H₂O₂ and those by BPMB. This observation indicated that BPMB induced covalently-linked STAT3 complexes that were different from H₂O₂-induced disulfide-linked STAT3 oligomers.

Modification of Cys550 within the Linker Domain of STAT3 by BPMB BPMB contains two quinoid moieties in the structure (Fig. 1a). Based on the chemical reactivity of the quinoid moieties, we predicted that BPMB could modify STAT3 proteins through alkylation and thereby inhibit the transcriptional activity of STAT3. To gain more insight into the biochemical interaction, we examined the effect of BPMB on purified rhSTAT3 in vitro. Biotinylated rhSTAT3 purified by His-tag dependent Ni-affinity chromatography was used for further biochemical analysis. Incubation of BPMB with rhSTAT3 for 1 h on ice resulted in the generation of the shifted bands migrating in the range 140–250kDa, as detected by an avidin-HRP conjugate for biotin-based detection (Fig. 4a).

Interestingly, we observed unusual retarded bands with masses corresponding to around 140–250kDa in immunoprecipitates from cell lysates of MDA-MB-231 and MDA-MB-468 cells treated with BPMB (Fig. 2b). However, retarded bands were not detected in MDA-MB-453 or MCF7 cells. The components of these high-molecular weight bands were not separable on SDS-PAGE and were recognized by the anti-STAT3 antibody. They are, therefore, SDS-resistant protein complexes harboring STAT3.

Characterization of the STAT3-Containing Complexes Induced by BPMB The formation of STAT3/1 and STAT3/5 heterodimers has been reported to be induced by several cytokines. To examine whether the complexes induced by BPMB contain STAT1 and/or STAT5, we analyzed the component immunoprecipitated with an anti-STAT3 antibody from HeLa

Fig. 2. Inhibition of Cell Proliferation and STAT3-Containing Large Complex Formation by BPMB in the Cell Lines with High Levels of P-STAT3 (a) Inhibition of cell proliferation by BPMB in the cells with high P-STAT3. Each cell line was treated with BPMB for 72 h and processed for WST-8 assays as described in Materials and Methods. Each point represents the mean from three replicates, and the error bars represent the standard deviation from the mean. Values analyzed by one-way ANOVA followed by Tukey's multiple comparisons test (**p < 0.01). (b) STAT3-containing large complexes were formed in human cancer cells with high levels of P-STAT3. Each cell line was treated with or without 10µM BPMB for 1 h. The STAT3-containing large complexes that precipitated with anti-STAT3 antibody were detected with anti-STAT3, or anti-P-STAT3 (Tyr705) immunoblotting. (Color figure can be accessed in the online version.)
Fig. 3. STAT3 Complexes Induced by BPMB Were Not Labile in the Presence of DTT

(a) STAT3-containing complexes do not contain STAT1 or STAT5. HeLa cells were incubated with 50 µM BPMB for 1 h, and then were stimulated with OSM for 30 min. STAT3-containing large complexes that precipitated with STAT3 were visualized by anti-STAT3, anti-STAT1, or STAT5 immunoblotting. (b) The stabilities of the STAT3-containing complexes under reducing conditions. The complexes induced by BPMB (50 µM) or H2O2 (500 mM) in HeLa cell lysates were incubated in a buffer containing 100 mM DTT.

Fig. 4. Sensitivity of the C550A STAT3 Mutant to BPMB

(a) Biotinylated rhSTAT3 was treated or not with BPMB (0.01–10 µM) for 1 h and the mixture was analyzed by blotting with streptavidin–HRP. (b) The mass signals at m/z 6057.85, corresponding to the untreated peptides (top of the mass signals) and treated peptides (bottom of the mass signals) in reflectron mode. (c) Representation of two 532–557 peptide fragments with bifunctional bound BPMB. The locations of the cysteine residues in STAT3 are indicated above. (d) Biotinylated rhSTAT3 and C550A mutant STAT3 were treated or not with BPMB (1 µM) for 1 h at 4°C and analyzed by Western blotting with streptavidin–HRP conjugate.
3). The results indicated that the shifted main band corresponded to STAT3 homodimer crosslinked by BPMB through a bifunctional covalent reaction with Cys550 in the linker domain of STAT3 (Fig. 4c). Our MALDI-MS analysis suggested that Cys550 could be an important primary target cysteine on STAT3. To better understand the role of Cys550, we assessed the effect of BPMB on a recombinant STAT3 protein with an alanine replacing Cys550. This mutant recombibant STAT3 was prepared and evaluated using the gel retardation assay. In the presence of 1 μM BPMB, the intensities of the retarded bands were decreased for the C550A mutant (Fig. 4d). These results demonstrated that Cys550 is an important residue for the formation of STAT3 homodimer crosslinked by BPMB in vitro.

DISCUSSION

Drugs that covalently modify their targets are rarely considered when attempting target-directed drug discovery, largely due to safety concerns and off-target reactivity problems. However, irreversible inhibitors such as ibrutinib, neratinib, and osimertinib have recently been widely used and studied because of their numerous advantages, including increased biochemical efficacy, longer duration of action, and the potential to inhibit processes that are often drug resistant. Several thiol modifiers have been reported to inhibit STAT3 functions, and one of these, namely, static, alkylates Cys251, Cys259, Cys367, and Cys426 in unphosphorylated STAT3. Moreover, galiellalactone binds to Cys367, Cys468, and Cys542 in unphosphorylated STAT3 and C48 (NSC-368262) modified Cys468. The C-28 methyl ester of the oleane triterpenoid 2-cyano-3,12-dioxooleana-1,9-dien-28-oic acid (CDDO-Me) inhibits STAT3 dimerization by binding to Cys259. S3I-201 modifies five cysteines (Cys108, Cys259, Cys367, Cys468, and Cys687) in the full-length STAT3 protein. Furthermore, curcumin interacts directly with Cys259.

In this report, we identified BPMB as a novel STAT3 inhibitor due to its ability to inhibit STAT3 dependent transcriptional activity in the luciferase reporter assay (Fig. 1b). BPMB contains two quinoid moieties for acting as Michael acceptors (Fig. 1a). MALDI-MS analysis suggested that BPMB undergoes a Michael reaction with Cys550, generating a crosslinked STAT3 homodimer (Fig. 4c). Indeed, the C550A mutant was insusceptible to BPMB modification as assessed by the gel retardation assay (Fig. 4d). The Cys550 residue is located within the STAT3 linker domain and has been reported to be involved in several functions such as STAT3 DNA binding, transcriptional activity, nuclear export, and protein–protein interactions.

Taken together, Cys550 is likely a key residue for the intermolecular crosslinking of STAT3 followed by the inhibition of STAT3 function by BPMB. The reason why BPMB selectively alkylates Cys550 remains to be elucidated. The proximity effect in a reaction environment would possibly assist the Michael addition. To date, there have been no reports of Cys550-interacting STAT3 inhibitors. Thus, our findings suggest that Cys550 could be one of the important drug targets for the future development of new irreversible STAT3 inhibitors. However, we could still not exclude the possibility of the modification of other cysteines of STAT3 by BPMB.

Sobotta et al. reported that a H₂O₂-inducing redox relay generates disulfide-linked STAT3 dimers and tetramers with attenuated transcriptional activity. The STAT3-containing large complexes induced by BPMB were SDS-resistant and stable under reducing conditions, unlike the labile complexes induced by H₂O₂ (Fig. 3b). These results support the BPMB-mediated covalent linkage of STAT3 and exclude the possibility of the disulfide linkages in STAT3 complexes. As reported previously, H₂O₂ induces the formation of STAT3 oligomers in the absence of STAT3-activating cytokines. On the other hand, the BPMB-induced STAT3 complexes could be detected only by using cells with high levels of P-STAT3 (Figs. 2b, 3a). As shown in Fig. 3a, there was negligible contamination with STAT3/STAT1 or STAT3/STAT5 hetero-complex; thus, the large complexes are likely STAT3 dimers and tetramers covalently crosslinked with BPMB. Alternatively, they might be hetero-complexes of phosphorylated STAT3 with other unknown binding partners. We demonstrated that BPMB attenuated STAT3-dependent transcription in the luciferase reporter assay in HeLa cells stimulated with OSM, despite no effect to phosphorylation status or nuclear translocation (Fig. 1). The STAT3-containing complexes induced by BPMB were detected only in cell lines with high levels of Tyr-phosphorylated STAT3 (Fig. 2b). In addition, BPMB selectively inhibited the proliferation of cancer cell lines with high levels of Tyr-phosphorylated STAT3 (Fig. 2a). These results support the hypothesis that the STAT3-containing complexes were no longer functional and were unable to activate the transcription of target genes. Our results to date have partially revealed the mechanism by which BPMB inhibits STAT3. The mechanisms underlying BPMB-mediated STAT3 inhibition are possibly more complex than those described in this study, thus further investigation will be necessary to elucidate the precise mechanisms, especially in cellular systems.

In conclusion, we identified a benzoquinone derivative BPMB as a direct inhibitor of STAT3 and demonstrated its unique mode of action to form stable STAT3 complexes in cells. The Cys550 residue within the linker domain is likely critical for the inhibition of STAT3 function. Thus, BPMB might be a useful tool for designing the next generation of STAT3 inhibitors.
