INTRODUCTION

Mast cells are closely related to allergic diseases such as asthma and atopic dermatitis and play essential roles in the allergic responses. Mast cells express the type I Fc epsilon receptor (FcεRI) that forms a complex with antigen-specific immunoglobulin (Ig) E. When IgE-sensitized mast cells are stimulated with antigens, various allergic mediators, such as histamine, cytokines, and eicosanoids are secreted from mast cells and induce allergic reactions. Activated mast cells also release β-hexosaminidase with the release of various allergic mediators. β-Hexosaminidase is stored in the secretory granules of mast cells, and it is commonly used as a marker of degranulation. Mast cells produce various cytokines, such as interleukin (IL)-4 and tumor necrosis factor (TNF)-α, which are critical in the inflammatory responses of late-phase reactions.

When antigens trigger IgE-sensitized mast cells, spleen tyrosine kinase (Syk) is activated. Syk is considered an important molecule in the allergic response associated with FcεRI signaling. The activation of Syk activates the phospholipase (PL) Cγ and causes the mobilization of calcium, which is essential for degranulation. The activation of Syk also causes the activation of downstream signaling molecules such as Akt and mitogen-activated protein kinases (MAPKs). MAPKs consist of the extracellular signal-regulated kinase (ERK) 1/2, p38, and c-Jun N-terminal kinase (JNK). The Akt and MAPK pathways play a crucial role in the expression of cytokines.

Selenium is an essential trace element for the health of humans and animals, and we are ingested through the consumption of food. Selenium is an element constituting the selenoproteins, through which its biological effects are primarily exerted. Glutathione peroxidase (GPx) and thioredoxin reductase are well-known selenoproteins, and they work to protect against oxidative stress. Seleno-L-methionine (SeMet) is an organic selenium compound and is one of the major selenium chemical forms contained in food. SeMet shows greater bioavailability and milder toxicity than inorganic selenium compounds. Therefore, SeMet is considered to be one of the most useful chemical forms for nutritional supplementation.

People suffering from allergic diseases have been reported to have significantly lower selenium concentrations and significantly lower GPx activity in blood than healthy individuals. In addition, according to a cohort study on atopic dermatitis, low selenium levels increase the risk of atopic dermatitis. It has been reported that an increase in oxidative stress is related to the pathogenesis of allergic diseases such as atopic dermatitis. Moreover, it has also been reported that an increase in oxidative stress is related to the activation of mast cells. From these considerations, we speculated that selenium could aid the prevention of allergic diseases. We have previously reported that supplementation with SeMet suppresses immediate allergic reactions stemming from ovalbumin-induced active cutaneous anaphylaxis (ACA) reactions in mice. Moreover, we also revealed that supplementation with SeMet suppresses chronic allergic reactions resulting from atopic dermatitis induced by repeated application of 2,4,6-trinitrochlorobenzene (TNCB) in mice. However, the effect of SeMet on IgE-mediated allergic response in mast cells has yet to be understood.

Rat basophilic leukemia (RBL-2H3) cells have structural and functional characteristics of mast cells, and have been commonly used in cell biological and biochemical researches of mast cell function. In this study, to clarify the effect of...
SeMet on IgE-mediated allergic responses of mast cells, we investigated the effects of SeMet on antigen-induced degranulation and cytokine expression in IgE-sensitized RBL-2H3 cells. In addition, the effects of SeMet on the antigen-induced mobilization of calcium and activation of Syk, Akt, and MAPKs in IgE-sensitized cells were also investigated.

MATERIALS AND METHODS

Reagents  Dinitrophenyl-human serum albumin (DNP-HSA), Anti-DNP-IgE, 4-nitrophenyl N-acetyl-β-D-glucosaminide, minimum essential medium (MEM) were provided by Sigma-Aldrich (St. Louis, MO, U.S.A.). SeMet was provided by Acros Organics (Geel, Belgium). Methionine (Met) was provided by Wako Pure Chemical Industries, Ltd. (Osaka, Japan).

Cell Culture  RBL-2H3 cells were provided by the National Institutes of Biomedical Innovation, Health and Nutrition (Osaka, Japan). Cells were maintained in MEM containing 10% heat-inactivated fetal bovine serum, 100 U/mL penicillin at 37°C in air containing 5% CO2. Cells were seeded into plates, settled for 3 h, treated with or without SeMet or Met, and incubated for 24 h. After incubation, anti-DNP IgE (0.2 µg/mL) was added and incubated for another 24 h. Then, this SeMet and IgE-treated cells were used for each experiment.

Cell Viability Assay  Cells were treated with the antigen DNP-HSA (20 ng/mL) for 2 h, followed by 3-(4,5-dimethyl-2-thiazolyl)-2,5-diphenyltetrazolium bromide (MTT) solution. After incubation for 4 h, the medium was removed, dimethyl sulfoxide was added, and the absorbance at 550 nm was measured by SH-1000Lab microplate reader (Corona Electric Co., Ltd., Ibaraki, Japan).

Measurement of β-Hexosaminidase Release  β-Hexosaminidase release was performed as described by Murata et al.20 with slight modifications. Briefly, the medium of the cells was replaced with siraganian (+) buffer (119 mM NaCl, 25 mM PIPES, 5.6 mM glucose, 1 mM CaCl2, 5 mM KCl, 0.4 mM MgCl2, 0.1% bovine serum albumin (BSA), and 40 mM NaOH, pH 7.2) and incubated for 30 min at 37°C and 5% CO2. Cells were treated with the antigen DNP-HSA (20 ng/mL) for 30 min at 37°C and 5% CO2, then the supernatant was collected, and the cells were lysed using siraganian (+) buffer supplemented with 0.1% Triton X-100. The cell lysates or the supernatants were transferred to a 96-well plate, and the cell viability was measured by SH-1000Lab microplate reader (Corona Electric Co., Ltd., Ibaraki, Japan).

Measurement of Calcium Mobilization  Calcium mobilization was measured by the Calcium Kit-Fluo 4 (Dojindo Laboratories, Kumamoto, Japan), which was performed in accordance with the manufacturer’s instructions. Briefly, cells were treated with Fluo 4-AM for 1 h, then the antigen DNP-HSA (20 ng/mL) was added via an injector of TriStar microplate reader (Berthold Technologies, Bad Wildbad, Germany), and the fluorescence intensity was measured (Excitation: 485 nm/ Emission: 535 nm).

RNA isolation and Real-time quantitative PCR  Cells were treated with the antigen DNP-HSA (20 ng/mL) for 2 h. RNA isolation and real-time quantitative PCR was performed as described in our previous study.7) The denaturation was carried out at 95°C for 10 s. The annealing condition was as follows: ribosomal protein S18 (Rps18); 60°C for 10 s; IL-4: 60°C for 20 s; TNF-α: 55°C for 10 s. The extension condition was as follows: Rps18 and TNF-α; 72°C for 10 s; IL-4: 72°C for 30 s. The cycle condition was 5 cycles. The results are expressed as the relative mRNA level compared with the expression of Rps18 mRNA. Primer sequences used were as follows: Rps18 forward: 5'-AAAGTTCAGCACATCTGGTGAGTA-3', and Rps18 reverse: 5'-TTTGTGGAGCTATGTTCTGTTTC-3'; IL-4 forward: 5'-ACCTTCGTGTCCTCTGGTGTC-3'; IL-4 reverse: 5'-CGCGTCAGTATGAGAGT-3'; TNF-α forward: 5'-AGCACTTCTGCCGTATGACG-3'; TNF-α reverse: 5'-GGGCTCTGACTGAGTGTGT-3'.

Measurement of IL-4 and TNF-α Proteins  Cells were treated with the antigen DNP-HSA (20 ng/mL) for 2 h, and the cell culture supernatant was collected. The amount of IL-4 and TNF-α in the cell culture supernatant were determined by enzymelinked immunosorbent assay (ELISA) (IL-4: Thermo Fisher Scientific, Waltham, MA, U.S.A.; TNF-α: BioLegend, San Diego, CA, U.S.A.) according to the manufacturer’s instructions.

Western blot analysis  Cells were treated with the antigen DNP-HSA (20 ng/mL) for 10 min. Western blot analysis
was performed as described in our previous study. Membranes were incubated with antibodies against phospho-Syk (Tyr525/526) (C87C1), Syk (D3Z1E), phospho-Akt (Ser473) (D9E), Akt (C67E7), phospho-ERK1/2 (D13.14.4E), ERK1/2 (137F5), phospho-p38 (D3F9), p38 (D13E1), phospho-JNK, JNK (Cell Signaling Technology, Danvers, MA, U.S.A.), and β-actin (AC-15) (Sigma-Aldrich). After incubation with secondary antibody, the protein expressions were detected using ECL reagent (GE Healthcare, Oxford, U.K.) and ChemiDoc MP (Bio-Rad Laboratories, Hercules, CA, U.S.A.). Quantitative Western blot data were obtained using Image Lab software (Bio-Rad Laboratories).

Statistical Analysis Statistical analysis was conducted by one-way ANOVA with the Bonferroni post hoc test. Origin Pro 9.0J software (LightStone Corp., Tokyo, Japan) was used for statistical analysis.

RESULTS

Effect of SeMet on β-Hexosaminidase Release and Calcium Mobilization We first measured the effect of SeMet treatment on the viability of RBL-2H3 cells. As shown in Fig. 1A, cell viability was not affected by SeMet treatment at increasing concentrations up to 10 µM.

To investigate the effect of SeMet on degranulation, β-hexosaminidase release, a general marker of degranulation, was measured. Cells were treated with or without SeMet, sensitized with IgE, and stimulated with antigen. As shown in Fig. 1B, β-hexosaminidase release was significantly increased upon antigen stimulation of IgE-sensitized cells compared with levels in negative control cells. Increase in β-hexosaminidase release by antigen stimulation was inhibited by SeMet treatment in a dose-dependent manner and was suppressed 28% at a concentration of 10 µM of SeMet. Antigen-induced β-hexosaminidase release was not significantly inhibited by 10 µM of Met. Since β-hexosaminidase release...
was most effectively suppressed at a concentration of 10 µM of SeMet, SeMet was used at a concentration of 10 µM in subsequent experiments.

We also measured calcium mobilization, which is involved in the regulation of degranulation. Cells were treated with or without SeMet and sensitized with IgE. The cells were then treated with Fluo 4, a fluorescent calcium probe, and stimulated with antigen. The fluorescence intensities for 3 min from the time of antigen stimulation were shown in Fig. 2. These results indicated that the fluorescence intensities, which are indicated the intracellular calcium levels, were increased by antigen stimulation in IgE-sensitized cells, and showed the highest value of about 1 min after antigen stimulation. Increase in fluorescence intensity by antigen stimulation was significantly suppressed by SeMet treatment, and was 34% lower with SeMet treatment at 1 min after antigen stimulation.

**Effect of SeMet on the mRNA Expression and Protein Secretion of IL-4 and TNF-α**

The effect of SeMet on the mRNA expression and protein secretion of IL-4 and TNF-α was measured. Cells were treated with or without SeMet, sensitized with IgE, and stimulated with antigen. After incubation, the cells were used for real-time quantitative PCR analysis, while the supernatant was used for ELISA. As shown in Figs. 3A and B, the expression of IL-4 and TNF-α mRNA was upregulated upon antigen stimulation in IgE-sensitized cells. Increase in IL-4 and TNF-α mRNA expression level by antigen stimulation was 31 and 66% suppressed by SeMet treatment, respectively. In addition, as shown in Figs. 4A and B, IL-4 and TNF-α protein secretion from antigen-stimulated IgE-sensitized cells was also increased. Increases in IL-4 and TNF-α protein secretion after antigen stimulation were 23 and 55% lower, respectively, due to SeMet treatment.

**Effect of SeMet on the Phosphorylation of Syk, Akt, and MAPKs**

To elucidate the effect of SeMet on the activation of Syk, Akt, and three MAPKs, the phosphorylation levels of Syk, Akt, and three MAPKs were investigated. Cells were treated with or without SeMet, sensitized with IgE, and stimulated with antigen. As shown in Fig. 5, the phosphorylation level of Syk was significantly increased by antigen stimulation in IgE-sensitized cells and was significantly decreased by SeMet treatment. In addition, the phosphorylation levels of Akt, ERK1/2, p38, and JNK were also significantly increased by antigen stimulation in IgE-sensitized cells and were significantly decreased by SeMet treatment.

**DISCUSSION**

We previously reported that the administration of SeMet suppressed immediate allergic reactions and chronic allergic reactions in mice. However, the effect of SeMet on the IgE-mediated allergic response in mast cells is yet to be elucidated. Our present data demonstrate that SeMet suppresses the antigen-induced allergic response in IgE-sensitized RBL-2H3 cells.
We first investigated the effect of SeMet on cell proliferation by MTT assay. As the growth of RBL-2H3 cells was not affected by 10 µM SeMet, we used 10 µM SeMet in this study. It has been reported that human blood selenium levels are 1 to 2.5 µM under normal circumstances and rise to 10 µM in people who ingest selenium supplements.22,23)

As a marker of degranulation of mast cells, β-hexosaminidase release is commonly well used.5) In this study, the release of β-hexosaminidase significantly increased upon antigen-stimulation in IgE-sensitized cells. Antigen-induced β-hexosaminidase release was significantly suppressed by SeMet treatment in a dose-dependent manner, and it was most inhibited at a concentration of 10 µM of SeMet. Antigen-induced β-hexosaminidase release was not suppressed by 10 µM of Met (same concentration as SeMet). According to the manufacturer’s information, the medium (MEM, #M0268, Sigma-Aldrich) used in this experiment originally contains 100.5 µM Met; the addition of 10 µM of Met is considered to be small and not to affect the degranulation. In addition, there is no report that 10 µM of Met suppresses degranulation or allergic responses. Therefore, we considered that SeMet suppressed degranulation at 10 µM, not Met.

It is well-known that mast cell degranulation is closely related to calcium movement.7) A transient increase of the intracellular calcium concentration occurs upon mast cell activation. The blockage of calcium levels changes attenuates degranulation. In this study, calcium mobilization was significantly increased upon antigen-stimulation in IgE-sensitized cells and was significantly inhibited by SeMet treatment. These results hint that SeMet-mediated suppression of calcium mobilization impairs degranulation.

Cytokines such as IL-4 and TNF-α are deeply involved in allergic reactions. IL-4 is essential for the production of IgE, and also involved in allergic-type T-helper (Th) 2 cells development.24) TNF-α is a potent proinflammatory mediator that is generated and secreted upon antigen stimulation in IgE-sensitized mast cells.25,26) We evaluated the effect of SeMet on mRNA expression and protein secretion of IL-4 and TNF-α upon antigen stimulation in IgE-sensitized cells. SeMet suppressed the antigen-induced upregulation of IL-4 and TNF-α mRNA in IgE-sensitized cells and decreased the protein secretion of IL-4 and TNF-α as well. These results imply that SeMet exerts anti-allergic effects by controlling cytokine levels in RBL-2H3 cells.

Syk is a crucial molecule in mast cell activation associated with FceRI signaling and is considered one of the promising therapeutic targets for allergic diseases.27) Syk activation is an important prerequisite for FceRI-mediated mast cell activation.28) The activation of Syk increases the mobilization of calcium,29) and also activates downstream signaling molecules such as Akt and MAPKs.30) Phosphorylation of Akt and MAPKs in mast cells has been reported to be associated with the expression of cytokines such as IL-4 and TNF-α.4) Although the activation of MAPKs by stimulation such as Staphylococcus aureus has been reported to be suppressed by selenium,31) the effect of selenium on the activation of MAPKs by antigen stimulation in IgE-sensitized mast cells is not well known. In this study, antigen-induced activation of Syk was significantly attenuated by SeMet treatment. Moreover, antigen-induced activation of Akt and MAPKs, which are downstream molecules of Syk, was also suppressed by SeMet treatment. From these results, it is suggested that Syk may be one of the target molecules of SeMet. It has been reported that an increase in oxidative stress contributes to the activation of mast cells.55) Furthermore, some reports showed that an increase in oxidative stress is also involved in the activation of Syk, Akt, and MAPKs.32,33) Since it is well known that selenium plays a vital role in defense of oxidative stress,34,35) SeMet may inhibit the activation of Syk via a cellular antioxidant system and inhibit allergic reactions by IgE antigen complexes.

In conclusion, our present study demonstrates that SeMet suppresses antigen-induced degranulation, and mRNA expression and protein secretion of IL-4 and TNF-α, and inhibits antigen-induced mobilization of calcium and activation of Syk, Akt, ERK1/2, p38, and JNK in IgE-sensitized RBL-2H3 cells. Our results provide valuable information that may be useful in the prevention and treatment of allergic diseases. Further studies are needed to elucidate the mechanism of the control of allergic reactions by SeMet.

Acknowledgments This research was supported in part by a Grant-in-Aid for Young Scientists (B) (JP15K18912) from the Japan Society for the Promotion of Science.
