Summary

Six triterpenic acids were separated and purified from the ethyl acetate extractive fraction of ethanol extracts of *Potentilla parvifolia* Fisch. using a variety of chromatographic methods. The neuroprotective effects of these triterpenoids were investigated in the present study, in which the okadaic acid induced neurotoxicity in human neuroblastoma SH-SY5Y cells were used as an Alzheimer’s disease cell model *in vitro*. The cell model was established with all trans-retinoic acid (5 μmol/L, 4 days) and okadaic acid (40 nmol/L, 6 hours) treatments to induce tau phosphorylation and synaptic atrophy. Subsequently, the neuroprotective effects of these triterpenic acids were evaluated *in vitro* by this cell model. Results from the western blot and morphology analysis suggested that compounds 3–6 had the better neuroprotective effects. Furthermore, we tested the level of mitochondrial reactive oxygen species and mitochondrial membrane potential of these compounds in SH-SY5Y cells by flow cytometry technology to investigate the potential neuroprotective mechanism of these compounds. All of the results indicated that maybe the mechanism of compounds 5 and 6 is to protect the cell from mitochondrial oxidative stress injuries.

Keywords

*Potentilla parvifolia*; triterpenic acids; SH-SY5Y cells; tau phosphorylation; reactive oxygen species
Alzheimer’s disease (AD) is a complex neurodegenerative disease, which happens in elderly people worldwide, characterized by progressive cognitive impairments and severe irreversible behavioral abnormalities. One of the most important hallmark of neuropathological lesions in AD is the intracellular neurofibrillary tangles (NFTs) which are composed of microtubule-associated protein tau protein in an abnormal phosphorylated form, but the mechanism of tau hyperphosphorylation in AD is still unclear.\textsuperscript{1,2} Human neuroblastoma SH-SY5Y cell lines can be differentiated from a neuroblast-like state into mature human neurons by being treated with a variety of differentiation agents, such as neurotrophic factors retinoic acid or phorbol ester, or staurosporine, or brain-derived neurotrophic factor.\textsuperscript{3,4} Okadaic acid (OA) is a potent inhibitor of Ser/Thr phosphatases, it can induce hyperphosphorylation of tau protein in SH-SY5Y cells that are similar to the phenomenon found in AD, therefore, it can be considered as a research model of AD.\textsuperscript{1} Moreover, OA-induced neurotoxicity plays a relative crucial role in AD. Thus, the neuroprotection against OA-induced toxicity for preventing and/or treating AD should be studied further. It is well known that mitochondrial dysfunction is an important early event in the development of AD.\textsuperscript{5} Mitochondria are not only responsible for ATP production, but also are a major source of reactive oxygen species (ROS) and oxidative stress and key contributors to aging and neurodegenerative disorders. Mitochondrial dysfunction and oxidative stress are known to be implicated in AD pathogenesis.\textsuperscript{6,7}

\textit{Potentilla parvifolia} Fisch. (Rosaceae) is known as a traditional Tibetan and Chinese medicine in China.\textsuperscript{8,9} It is widely distributed in many provinces of China, such as Heilongjiang, Inner Mongolia, Shanxi, Gansu, Qinghai, Sichuan, Tibet and Xinjiang.\textsuperscript{8,10,11}
The aerial parts of this plant (especially the leaves and flowers) are used for the treatment of skin diseases, mastitis, breast cancer, beriberi and edema. However, there are few reports on its chemical compositions and the related biological activities. Phytochemical studies on Potentilla revealed that triterpenes, flavonoids and tannins are the main important constituents of these plants. It is reported that triterpenes have shown neuroprotective activities. Herein, we report the isolation of six triterpenic acids (1~6) from P. parvifolia. (Fig.1), and investigate their neuroprotective effects in vitro. To the best of our knowledge, all of the six compounds were isolated from P. parvifolia for the first time, and it is also the first report on the triterpenes chemical compositions from P. parvifolia.

In the present research, the in vitro AD cell model were established as described in our previous study: the human SH-SY5Y neuroblastoma cells were differentiated into mature neurons by treating with 5 μmol/L all trans-retinoic acid (ATRA), then the differentiated SH-SY5Y cells were treated with 40 nmol/L OA for 6 h to simulate the phosphorylation of tau, and this can induce changes similar to those occurring in vivo in AD. Herein, we evaluated the neuroprotective effects of the six triterpenic acids from P. parvifolia against OA induced tau phosphorylation in SH-SY5Y cells in vitro by the above cell model. Furthermore, we evaluated the potential neuroprotective mechanism of these compounds in SH-SY5Y cells which were mainly related to the mitochondria. This is the first investigation on the screening of neuroprotective activity of the triterpenes components in P. parvifolia.

MATERIALS AND METHODS

**Plant Material** The aerial parts of P. parvifolia were collected from Haibei Prefecture of Qinghai, China, in August 2014. Affirmative identification of the plant was provided by Dr.
Faqi Zhang (Northwest Institute of Plateau Biology, Chinese Academy of Sciences, Xining, China), and the plant was authenticated using the voucher specimen in the Qinghai-Tibetan Plateau Museum of Biology (Xining, China) (reference No. 252558).

**Isolation of the six triterpenic acids** Details of the extraction have previously been reported.17) Briefly, dried powdered aerial parts of *P. parvifolia* (6.5 kg) were extracted with 70% ethanol and partitioned with petroleum ether, EtOAc and n-BuOH respectively, yielding a EtOAc extract (103 g) and a BuOH extract (97 g) after removal of the solvent by evaporation. The EtOAc extract was fractionated via silica gel (100-200 mesh) column chromatography and based on the gel TLC, the resulting elutes were combined into 9 fractions (Sh1-Sh9). Fraction Sh2 (9.7 g) was passed through a silica gel (160-200 mesh) column, eluting with a gradient of petroleum ether: ethyl acetate (10:1, 8:1, 6:1, 5:1, 3:1, 2:1, 1:1), to give 7 fractions (Sh2-1–Sh2-7). Fraction Sh2-2 was separated by Sephadex LH-20 gel, eluting with CHCl3-CH3OH (2:1), yielding 5 fractions (Sh2-2A–Sh2-2E). Fraction Sh2-2B was purified by a silica gel (200-300 mesh) column, eluting with a gradient of CHCl3-CH3OH (100:1, 80:1, 50:1, 40:1, 30:1, 20:1, 10:1, 5:1, 2:1), yielding compounds 1 (150 mg, 98.1%) and 2 (350 mg, 98.6%). Fraction Sh2-3 was fractioned via a silica gel (160-200 mesh) column chromatography, eluting with a gradient of petroleum ether: ethyl acetate (50:1, 40:1, 30:1, 20:1, 10:1, 5:1), to afford 5 fractions (Sh2-3A), Fraction Sh2-3A was further purified by Sephadex LH-20 gel respectively, eluting with CHCl3-CH3OH (2:1), and further purified via a silica gel (200-300 mesh) column chromatography, eluting with a gradient of CHCl3: CH3OH (40:1, 30:1, 20:1, 10:1, 5:1, 2:1), yielding compounds 3 (5 mg, 96.0%) and 4 (70 mg, 97.7%). Fraction Sh2-6 was subjected to a silica gel (160-200 mesh)
column, eluting with a gradient of petroleum ether: ethyl acetate (40:1, 30:1, 20:1, 10:1, 5:1), and further purified by Sephadex LH-20 gel, eluting with CHCl₃-CH₃OH (2:1), to afford Fraction (Sh2-6C). Fraction Sh2-6C was further subjected to a silica gel (200-300 mesh) column, eluting with CHCl₃-CH₃OH (30:1) to yield compound 5 (200 mg, 98.5%). The BuOH extract was fractionated via macroporous adsorption resin (AB-8) column chromatography, eluting with a gradient of increasing EtOH (0-95%) in H₂O, the resulting eluates were combined into 5 fractions (Sh1-Sh5). Fraction Sh3 (15 g) was chromatographed on MCI gel column, eluting with a gradient of CH₃OH:H₂O (15%, 30%, 50%, 80%, 100%), to afford Fractions (Sh3-5). Fraction Sh3-5 was subjected to preparative HPLC, eluting with CH₃OH-H₂O (3%) repeatedly, yielding compound 6 (24 mg, 96.4%).

**Cell culture** The SH-SY5Y cells (ATCC) were grown in Dulbecco’s modified Eagle’s medium (DMEM) supplemented with penicillin (100 IU/mL), streptomycin (100 μg/mL) and 10% (v/v) fetal bovine serum (FBS, Gemini, U.S.A.). Cells were maintained at 37 °C in a saturated humidity atmosphere containing 95% air and 5% CO₂. Experiments were initiated until cells grew to 60%-70% confluences. Cells were differentiated in the presence of 5 μmol/L ATRA (Aladdin, China) for 4 days in the cell medium and reducing the serum level to 1%. The medium was changed every 2 days. After four days’ differentiation, the medium was replaced with new DMEM with 40 nmol/L of OA (Sigma-Alorich) and 1% FBS.

**Cell viability assay** Cell viability was evaluated by MTT assay. SH-SY5Y cells were exposed to compounds 1~6 (0, 0.1, 1, 10, 50 and 100 μmol/L) separately for 24 h at 37 °C. Then 10 μL of MTT (5 mg/mL stock in PBS) was added to each well (96-well plate, 200 μL medium/well), and incubated for 4 h. The insoluble blue formazan was solubilized with 100
μL of DMSO, and OD values of the mixture were measured at 490 nm with a microplate reader (Molecular Devices, USA). MTT assays were set not less than 4 separate samples, which were measured in triplicate.

**Measurement of the synapses** Cells were observed and photoed in a phase-contrast microscope connected through a video camera to a computer running adequate image analyzer software (Leica Microsystems, Germany). The cell bodies and neurites present in 5 randomly selected fields were counted. The length of neurites and the diameter of cell bodies were scored manually by Image pro plus 6.0 software. The ratios between cell bodies and neurites were calculated yielding the average of neurites/bodies per neuron and expressed as the mean ± SEM value. Differences were considered to be significant when p < 0.05.

**Western blot assay** For western blot experiments, cells were washed twice with PBS, then lysed with RIPA buffer (50 mmol/L Tris-HCl (pH 7.4), 150 mmol/L NaCl, 1% NP-40, 0.1% SDS, 100 mg/mL Phenylmethyl Sulphonyl Fluoride (PMSF)) for 20 min, cells were harvested by scraping. Lysates were then centrifuged at 13,000 g for 10 min at 4 °C, and supernatants were collected for analysis. The protein concentration was measured in the supernatant using the BCA Protein Assay Kit. Protein from the treated cells was mixed with loading buffer, boiled for 5 min. Then, the protein (30 μg) was loaded into each lane of a 10% SD-polyacrylamide gel, separated by SDS-PAGE (Miniprotean; Bio-Rad) and then transferred to Immunobilon-P polyvinylidene difluoride (PVDF) (Millipore, Bedford, MA) membrane. Membranes were blocked with 5% non-fat dry milk in TBS Tris-buffered saline (10 mmol/L Tris-base, pH 7.5, 68 mmol/L NaCl) containing 0.1% Tween 20 for 1 h at room temperature. Proteins were probed with specific antibodies at proper dilutions according to
the manufacturer's instruction and incubated overnight at 4 °C. The blots were rinsed and subsequently incubated with peroxidase conjugated antibodies for 1 h at room temperature. Following washing, antibody binding were finally developed with the enhanced chemiluminescence western blotting detection system. Western blot bands were visualized using a 5200 Multi Luminescent image analyzer (Tanon Science & Technology Co., Ltd. Shanghai, China) and quantified by densitometry analysis using Image pro plus 6.0 software. The following antibodies were used at the dilutions recommended by the manufacturers: Tau-5 (Abcam, U.S.A.), p-Tau Ser262 (Abcam, U.S.A.), β-actin (Santa Cruz Biotechnology, U.S.A.), HRP Goat anti-Rabbit IgG Antibody and HRP Goat anti-Mouse IgG Antibody (Abgent, China).

Detection of mitochondrial reactive oxygen species levels The mitochondria-derived superoxide accumulation was measured using MitoSOX Red (Invitrogen, USA). MitoSOX Red was dissolved in DMSO to yield a 5 mmol/L stock and subsequently diluted to a working concentration of 5 μmol/L in warm PBS. Briefly, after the indicated treatments, cells were incubated in this MitoSOX Red solution at 37 °C for 30 min and MitoSOX Red fluorescence was then measured by flow cytometry. As a positive control, 1 μmol/L mitotempo were used by treating SH-SY5Y cells at 37 C for 30 min.

Measurement of mitochondrial membrane potential (ΔΨm) The fluorescent probe, JC-1 (Thermo Fisher Scientific, USA), was employed to measure the mitochondrial membrane potential (ΔΨm). Briefly, after the indicated treatments, cells were incubated with JC-1 staining solution (5 μg/mL) for 30 min at 37 °C. The mitochondrial membrane potential of SH-SY5Y cells were calculated as the fluorescence ratio of red to green. JC-1 fluorescence
was measured by flow cytometry. As a positive control, mitochondria were depolarized by treating SH-SY5Y cells with 10 μM carbonylcyanidem-chlorophenylhydrazone (CCCP) at 37 °C for 30 min.

**Statistical analyses** Data were expressed as the mean ± SEM of cell treatments from at least three independent experiments. Statistical significance was determined with SPSS 17.0 software using the Student’s t-test and values of \( p < 0.05 \) as significant.

RESULTS AND DISCUSSION

There are few reports about *P. parvifolia*, including the phytochemical study and pharmacological activity study. To study the chemical constituents of this plant comprehensively, in the present study, six triterpenic acids, oleanolic acid (1), betulinic acid (2), pomolic acid (3), platanic acid (4), euscaphic acid (5) and corosolic acid (6), were isolated from the aerial parts of *P. parvifolia*, and identified by the \(^1\)H NMR, \(^{13}\)C NMR spectra data and comparing with the literature reported.\(^{18-21}\) The purities of these compounds were tested by HPLC. This is the first time for the isolation of the six compounds from *P. parvifolia*.

Since elevated doses of plant compounds can act as pro-oxidants in cell culture systems and evoke cellular injury, it is necessary to ensure that no direct cell damage is caused by concentrations within the range of the tested compounds before investigating its protective effect.\(^{22}\) The concentration range of these six compounds was measured by testing the cell viability of SH-SY5Y cells by MTT assay. As shown in Fig.2, Compounds 1, 3-5 showed cytotoxicity to SH-SY5Y cells when its concentration was at 50 and 100 μmol/L and compound 2 showed cytotoxicity to the cells when the concentration was at 10~100 μmol/L.
Furthermore, compounds 2–4 showed a concentration dependence that with their concentrations increasing, the cell viability of SH-SY5Y cells decreased in the range of tested concentrations; compound 6 showed a not that obvious trend as compounds 2–4, but it did not affect the viability of SH-SY5Y cells that much. Therefore, in conclusion, at the concentrations of 0.1 μmol/L, all of these compounds had little cytotoxicity on the SH-SY5Y cells. And this can be an indication of the choice of the compounds’ concentrations.

To investigate the neuroprotective activities of the six triterpenic acids from *P. parvifolia*, firstly, the SH-SY5Y cells were treated with 5 μmol/L ATAR for four days, after the cells were differentiated to mature neurons, then the differentiated cells were co-treated with OA (40 nmol/L) and each of the compounds (100 nmol/L) for 6 h in DMEM with 1% FBS. Phosphorylation tau (Ser 262 site) was assessed via western blot analysis (Fig.3 A and B), and the lower expression of phosphorylated tau protein, the better of the neuroprotective against the OA induced neurotoxicity. The differentiated cells were used as black control, the OA treated differentiated cells as model group (OA group), and differentiated cells co-treated with OA (40 nmol/L) and LiCl (10 mmol/L) as positive control group (LiCl group). From the results of western blot, it can be seen that except compound 1, the phosphorylation levels of other compounds were lower than that of LiCl group in different degrees, and the phosphorylation levels of all the six compounds were lower than OA group. And all of the groups were compared to OA group (*p<0.05 and **p<0.01). The results showed that compounds 3–6 have the better protect effects. Furthermore, the results can be verified by the morphology results of the cells co-treated with the six compounds and OA (Fig.4 A and B). The results suggested that the six triterpenic acids all have neuroprotective activity against
OA-induced tau phosphorylation in varying degrees. Compounds 3~6 have the better effects. Above all, combined with the western blot analysis and morphology results, compounds 3~6 gave the better neuroprotective effects in preventing the neurotoxicity induced by OA in SH-SY5Y cells. And this result made a foundation for us to further study the compounds in *P. parvifolia*.

Mitochondria were a major site of generation of ROS and mitochondrial dysfunction was a prominent feature in cell death, and mitochondrial dysfunction leaded to mitochondrial ROS production and ΔΨᵡ loss. To investigate the mechanism of the neuroprotective effects of these compounds, the level of mitochondrial ROS and mitochondrial membrane potential (Δψᵡ) of these compounds in SH-SY5Y cells were tested by flow cytometry technology. The results showed that, after treated with OA, the mitochondrial ROS level was raised significantly compared with the control group, and that of the mitotempo group was reduced to 54.4% of the OA group. While, the Δψᵡ level of OA group was reduced to 83.3% of the control. Therefore, it can be seen from the above results that the model was successful (Fig.5 A and B). For the mitochondrial ROS level, all of the six compounds showed a lower level compared to the OA group, and compound 2 has a 47.6% level of OA group (P<0.01), compounds 5 and 6 showed a 51.5% and 55.3% level of OA group, respectively (P<0.05) (Fig.5 A). For the mitochondrial Δψᵡ level, all of the six compounds showed a higher level in comparison with the OA group, compounds 1, 5 and 6 significantly reversed the OA-induced the decrease of Δψᵡ (P<0.01) and compounds 2-4 has a rise level compared to OA group (Fig.5 B). The above results indicated that compounds 2, 5 and 6 may protect the mitochondria from damaging. In combination of the above results of western blot analysis
and morphology, compounds 5 and 6 may play an important role in protecting SH-SY5Y cells against OA-induced injury via the protection of mitochondria dysfunction.

Increasing reports suggested an important role of mitochondrial dysfunction and oxidative stress in the pathogenesis of AD. Furthermore, some data suggested that tau plays a key role in the pathogenic cascade. Tau pathology lead to reduced mitochondrial membrane potential reduced ATP levels, followed by enhanced ROS production. On the other hand, mitochondrial oxidative stress also can cause hyperphosphorylation of tau. Oxidative stress increases aberrant tau phosphorylation by activation of glycogen synthase kinase 3 (GSK-3). Maybe tau accumulation acts in synergy on oxidative stress and mitochondrial dysfunction, and both mitochondrial dysfunction and oxidative stress clearly play an important role in the pathogenesis of AD. Nevertheless, the precise mechanism of events in AD pathogenesis still remains uncertain.

Previous studies have shown that triterpenoids have the neuroprotective activities against MPP+-induced and glutamate-induced neurotoxicity. The results from the present study further suggested that triterpenoids have the neuroprotective effects. The results suggest that triterpenes from P. parvifolia attenuates mitochondrial dysfunction induced by OA, and such effects may play an important role in protecting SH-SY5Y cells against OA-induced cytotoxicity. These protective effects might be associated with improving mitochondrial function. These findings suggest a promising role of euscaphic acid and corosolic acid as a novel therapeutic strategy for AD. However, SH-SY5Y cells cannot totally represent the characters of primary cultured neurons, and further work needs to focus directly on primary neurons and in vivo models. Although there is no known clinical treatment that can stop or
reverse the progression of the disease completely, one approach is to investigate traditional herbs as possible natural therapeutic agents. In the present investigation, we isolated six triterpenic acids from P. parvifolia, and tested their neuroprotective effects by an in vitro AD cell model. These findings on the compounds of P. parvifolia possessing neuroprotective activities may provide some ideas for the development of agents to ameliorate cellular dysfunction due to OA induced toxicity. And these findings may give a foundation of the further study of P. parvifolia.
