ABSTRACT

Semaphorin4A (Sema4A) is a family member of semaphorins expressed in immune cells and is also related with disease progression of tumor disease. In this study, we investigate the expression and pathological role of Sema4A in breast cancer (BCa). Our data showed that the expression of Sema4A increased in the tissues and serum of BCa patients when compared with normal controls. The expression of Sema4A in BCa cells could be induced by hypoxic treatment, whereas silencing HIF-1α could attenuate the above induced. Furthermore, ChIP analysis demonstrated that HIF-1α could regulate the expression of Sema4A through directly binding to the promoter of Sema4A gene, whose enrichment could be further enhanced by hypoxic stimulation. In addition, silencing Sema4A could inhibit the proliferation, VEGF production and the phosphorylation of Akt, ERK1/2 MAPK and STAT3, but induce apoptosis of BCa cells in the presence of hypoxia. In contrast, recombinant human Sema4A treatment showed the opposite effects. Taken together, these results suggest that Sema4A could promote progression of BCa in the presence of hypoxia and it may hold potential for treatment target for BCa.

Keyword breast cancer, semaphorin, hypoxia, Sema4A
Semaphorins are originally identified to provide axon guidance cues for neural development.\textsuperscript{1)} Thus far, more than 30 Semaphorins have been found and they function through their receptors, called plexins.\textsuperscript{1)} In addition to its involvement in neural activity, Semaphorins are also related with the immune response and angiogenesis.\textsuperscript{2, 3)} Recently, mounting evidence showed that Semaphorins contribute greatly to tumor progression and hold potential for treatment targets in various tumors.\textsuperscript{3)}

Semaphorin 4A (Sema4A) is a family member of Semaphorins and exists in a transmembrane form. Its extracellular form could be proteolytically cleaved and behave as soluble ligand in extra-cellular compartment.\textsuperscript{4)} As a pathological factor, it contributes to human diseases, such as viral bronchiolitis,\textsuperscript{5)} asthma\textsuperscript{5)} and retinal degenerative diseases\textsuperscript{6)} and exerts its effect on T cell\textsuperscript{7)} and macrophage.\textsuperscript{8)} Our previous study found that the elevated level of Sema4A in the synovial fibroblasts of rheumatoid arthritis could exacerbate its inflammatory phenotype.\textsuperscript{9)} Furthermore, soluble Sema4A could also promote the invasive ability of synovial fibroblasts.\textsuperscript{9)} In hepatocellular carcinoma, Sema4A promoted doxorubicin-induced epithelial- mesenchymal transition (EMT).\textsuperscript{10)} Sun et al also reported that Sema4A acted as a receptor for Plexin-B1 to induce migration of different tumor cells.\textsuperscript{11)}

In this study, we aimed to characterize the expression and functional role of Sema4A in BCa cells and also investigate the pathological mechanism for the deregulated Sema4A in BCa.

MATERIALS AND METHODS

Collection of human tissue and serum from Breast cancer patients Human breast tumor and its adjacent non-cancerous tissues were obtained from Qilu Hospital of Shandong University (Jinan, China). The serum samples were collected from Zibo Central Hospital (Zibo, China). This study protocol was approved by the institutional Review Board of Research Center for Medicinal Biotechnology of Shandong and the informed written consent was also obtained from the patients. Our work is also in accordance with The Code Ethics of the World Medical Association (Declaration of Helsinki).
**Cell culture and siRNA transfection** MDA-MB-231 and MCF-7 were obtained from the American Type Culture Collection (ATCC, Manassas, VA, USA). Cells were cultured in DMEM or RPMI1640 supplemented with 10% heat-inactivated FBS at 37°C in 5% CO₂ atmosphere. For hypoxic treatment, cells were cultured in a 1% or 0.2% O₂ Anaerobic Glove Cabinet (Thermo Scientific) for 24 hour. For siRNA transfection, Sema4A small interfering RNA (50nM, SI00133560), HIF-1α (SI02664431), HIF-2α (SI02663038) and Negative control (SI03650318) were bought from QIAGEN (Hilden, Germany) and transfected in to BCa cells by Hyperfect transfection reagent (QIAGEN). Recombinant human Sema4A protein was bought from Abnova.

**ELISA** Sema4A in the patients’ serum and culture media were detected as described before.⁹ VEGF levels in culture supernatants were measured using ELISA kits provided by R&D Systems (Minneapolis, MD, USA).

**RNA and Reverse transcription and quantitative real-time PCR (qPCR)** Total RNA was extracted from cells using Trizol reagent (Invitrogen) and reversely transcribed into cDNA by with a reverse transcription kit (TOYOBO). Sema4A and VEGF were detected by qPCR using the following primer sequences: Sema4A forward: 5’-TAAAGTGAATGAAACCATTTGT-3’; reverse: 5’-GTCTGTGAAATGT TTTACAGTGT-3’; GAPDH forward: 5’-CACCATCTTCCAGGAGC-3’; reverse: 5’-AGTGGAATCCACCGACGTA-3’. The data shown were the relative changes as calculated by the 2-ΔΔCt method and GAPDH was the internal control.

**Western blot** Cells were lysed using lysis buffer (Beyotime, Shanghai, China) and the extracted protein was subjected to SDS-PAGE, followed by transfer on PVDF membrane. Then, membranes were blocked in 5% non-fat milk for 1 h at room temperature. After incubated with the primary antibody against Sema4A at 4°C overnight and HRP-conjugated anti-rabbit secondary antibody for 1 h at 37°C, proteins were visualized by ECL kit (Merck Millipore). p-Akt, Akt, pERK1/2 mitogen-activated protein kinase (MAPK), ERK1/2MAPK,
STAT3 and pSTAT3 were purchased from Cell Signaling (Boston, USA). Sema4A (Abcam) or glyceraldehyde-3-phosphate dehydrogenase (GAPDH) (Santa Cruz). Bound antibodies were revealed with horseradish peroxidase-conjugated secondary antibodies (Santa Cruz).

**Cell proliferation and apoptosis assay** After transfection with siRNA or hypoxic treatment, the proliferation of cells in 96-well plates was analyzed by CCK-8 Kit (Solabio). For apoptosis analysis, cells were stained for Annexin V (BestBio), counterstained with propidium iodide and measure by Flow Cytometry (BD, Accuri C6 Plus).

**ChIP-qPCR Assay** Chromatin immunoprecipitation (ChIP) was performed according to the manufacture’s instruction (Millipore). Input DNA was applied to normalize the enrichment of HIF-1α on the promoter of Sema4A gene and the specific binding was analyzed by qPCR using the primers as followings: forward: 5’-CTATTCACAGGCTTGATCA-3’; reverse: 5’-AAAATTAGTTCCACTCTT-3’. Anti-HIF-1α and irrelevant antibody (IgG) were from Abcam (Cambridge, MA, USA) and Millipore (Billerica, MA, USA), respectively.

**Statistical analysis** All statistical analyses were carried out using SPSS 16.0 (New York, NY, USA). All the experiments were repeated for at least three repeats independently. Student’s t-test was applied to evaluate the comparison of two independent groups. Data was expressed as mean ± SEM. P < 0.05 was considered significant.

**RESULTS**

**Sema4A expression increases in BCa** To clarify the functional role of Sema4A in BCa, we firstly analyzed its expression in BCa tissue as well as its adjacent non-cancerous tissues. The data showed that the expression of Sema4A at both RNA (Fig. 1A) and protein (Fig. 1B) levels are higher in BCa tissues when compared with its corresponding normal tissue.

It has been reported that Sema4A could be cleaved into the extracellular compartment and functions through its receptors. In this study, we also detect its expression in the serum of BCa patients by ELISA. The results showed that Sema4A expression was higher in the
serum of BCa patients when compared with healthy control ones (Fig. 1C), suggesting its potential role in BCa progression.

**Hypoxia induces Sema4A production in BCa cells through a HIF-1α dependent way**

Considering the elevated expression of Sema4A in BCa cells and hypoxia acts as an important contributor to BCa,\(^{12}\) we wonder the relation between hypoxia and Sema4A. MDA-MB-231 and MCF-7 cells are chosen as the model as they are frequently used when studying the relation between hypoxia and BCa.\(^{13-15}\) The data showed that the expression of Sema4A in BCa cells could be induced if the exposure of hypoxia (1% and 0.2% O\(_2\)) (Fig 2A-B). Intriguingly, the level of Sema4A in the supernatant was also upregulated after stimulation with hypoxia (Fig 2C-D).

As HIF-1α and HIF-2α are main effectors of hypoxia for tumor progression,\(^{12, 16}\) we subsequently analyzed the effect of HIF-1α or HIF-2α knocking down on the expression of Sema4A in BCa cells. The silencing efficiencies of siRNA targeting HIF-1α and HIF-2α were firstly detected in both cell lines (Fig. 2E). Following study showed that silencing HIF-1α, but not HIF-2α, could suppress the basal level of Sema4A in MDA-MB-231 (Fig. 2F, upper) and MCF-7 cells (Fig. 2F, lower). Of note, the induction of Sema4A in BCa cells in response to hypoxia (1% O\(_2\)) could be attenuated in the presence siRNA targeting HIF-1α, but not HIF-2α (Fig. 2G).

We also analyzed the expression of Sema4A in the supernatant of BCa cells. Consistent with endogenous Sema4A in BCa cells, the soluble Sema4A increased significantly after stimulation with hypoxia (1% O\(_2\)), while silencing HIF-1α could antagonize this increase (Fig. 2H). Together, hypoxia is account for the increased expression of Sema4A in BCa cells.

To further validate the effect of HIF-1α on Sema4A, Jaspar software was applied to predict the potential binding of HIF-1α on the promoter of Sema4A gene. Next, ChIP-qPCR was performed in MDA-MB-231 and MCF-7 cells and found that HIF-1α could bind to the region encompassing -697bp\(^{\sim}\) -706bp away from its transcriptional start point of Sema4A (Fig. 2I). Importantly, the recruitment of HIF-1α increased in response to hypoxic stimulation (Fig. 2I).
Sema4A is required for the activity of hypoxia towards BCa cells To evaluate the functional roles of Sema4A in BCa, siRNA targeting Sema4A was designed and the one showing the most silencing efficiency was selected for following study (Fig. 3A). Next, we measured the effect of Sema4A on the activity of hypoxia. The data showed that, in response to hypoxic treatment, the production of VEGF (Fig. 3B-C) and the phosphorylated levels of MAPK, Akt and STAT3 (Fig. 3D-E) increased significantly in MDA-MB-231 and MCF-7 cells. However, silencing Sema4A could attenuate the above increase caused by hypoxic stimulation (Fig. 3B-D). We then measured the effect of recombinant human Sema4a (rhSema4a) on the expression of VEGF under hypoxic condition. More interestingly, rhSema4A in combination of hypoxic treatments induced additive increase of VEGF production (Fig. 3C) as well as phosphorylated ERK, Akt and STAT3 when compared with hypoxia treatment alone (Fig. 3E).

Silencing Sema4A inhibits proliferation but induces apoptosis of tumor cells in the presence of hypoxia Before incubation with either normoxia or hypoxia (1% O2), MCF-7 and MDA-MB-231 cells were pre-treated with siRNA targeting Sema4A or its negative control for 6h. Then the cell proliferation rates were then assayed for a further 24h. The data showed that silencing Sema4A could reduce the cell proliferation rates in both normoxia and hypoxia (1% O2, Fig. 4A). More importantly, the suppression was more obvious in hypoxic condition (1% O2, Fig. 4A).

Next, we measured the effects of Sema4A on cell apoptosis under normoxic or severe hypoxic condition (0.2% O2) by Annexin V. The data demonstrated that silencing Sema4A made no obvious effects on cell apoptosis in normoxia (Fig. 4B). However, following Sema4A knocking down, the apoptosis increased dramatically in the presence hypoxia, although apoptosis could also be induced by hypoxic stimulation alone (Fig. 4B). Collectively, these data indicates that silencing Sema4A may inhibit the progression of BCa.

rhSema4A protects BCa cells against apoptosis induced by severe hypoxia To investigate that function of Sema4A in its soluble form, recombinant human Sema4A was applied to
detect its effects on the biological activity of BCa cells. The results showed that treatment with rhSema4A could up-regulate the cell proliferation of BCa cells, which could be further enhanced with the stimulation of hypoxia (1% O\textsubscript{2}) (Fig. 4C). We also applied severe hypoxia (0.2% O\textsubscript{2}) to induce more cell apoptosis and determine the effect of rhSema4A on it. The results showed that rhSema4A treatment could provide resistance to hypoxia-induced cell apoptosis (Fig. 4D).

**Discussion**

Recent study demonstrated the intense relation between Sema4A and tumor\textsuperscript{4, 10, 11}. It was shown that germline variants in the Sema4A gene could predispose to familial colorectal cancer type X\textsuperscript{17}. Sema4A could also promote the drug resistance in hepatocellular carcinoma\textsuperscript{11}. In BCa, Sema4A could regulate the migration of BCa cells through interacting with its receptor\textsuperscript{11}. However, the exact roles and its pathological mechanism in BCa remain unknown. In this study, our data revealed that Sema4A may promote the progression of BCa based on the following facts. Firstly, Sema4A expression is more abundant in BCa tissues than its adjacent non-cancerous ones. In addition, the serum levels of Sema4A are also higher in BCa patients than normal controls. Secondly, silencing Sema4A could inhibit the cell proliferation, but induce apoptosis of BCa cells. Tumor formation assay in vivo would be needed to further support its oncogenic role of Sema4A in BCa.

As the highly proliferative tumor cells require more oxygen consumption, hypoxia exits in the tumor microenvironment\textsuperscript{18}. Recently, it has been increasingly recognized that the tumor microenvironment is closely related with tumor progression and HIF-1\textalpha acts as the main regulator to adapt to intratumoral hypoxia\textsuperscript{18, 19}. Another finding in this study is the cross-talk between Sema4A and hypoxic activity. Our data showed that Sema4A expression is directly regulated by HIF-1\textalpha in the presence of hypoxia. Furthermore, Sema4A may act as an effector of BCa cells in response to hypoxia as demonstrated by the facts that the effects of Sema4A knocking-down on cell proliferation and apoptosis was more obvious in the presence of hypoxia. Besides, in response to hypoxia, the most important characteristics of BCa cells are the abnormal production of VEGF\textsuperscript{20} and the deregulated activation of Akt, MAPK and
Therefore, reduction of the above signaling may offer benefits in BCa therapeutic efficacy. Our results demonstrated that silencing Sema4A could effectively attenuate the production of VEGF, as well as the activation of Akt, MAPK and STAT3 with the stimulation of hypoxia, indicating its potential for treatment target. As administration of Sema4A could diminish the efficacy of IFN-β in experimental autoimmune encephalomyelitis, further study would also be needed to study the effects of Sema4A on chemo-sensitiveness of BCa cells.

High serum Sema4a levels were observed in multiple sclerosis (MS) and rheumatoid arthritis patients. Besides, Sema4A in its soluble form could also regulate the biological activity of synovial fibroblasts of rheumatoid arthritis (RASFs) as well. In this study, we also found that the secretion of Sema4A increased with the stimulation of hypoxia and soluble Sema4A, in turn, could regulate the biological activity of BCa cells, supporting its pathological activity in the microenvironment during tumor progression. Previous study demonstrated that Sema4A could enhance lung fibrosis via Plexin D1 receptor, but is required for optimal activation of mTORC1 in CD8(+) T cells through Plexin B2 receptor. These data suggest that Sema4A's functions differ from cell types and receptors and the receptor of Sema4A involving BCa needs to be clarified.

Taken together, these results indicate that hypoxic induction of Sema4A contributes to the abnormal proliferation and apoptosis of BCa cells. Specific targeting Sema4A may be a novel treatment avenue for BCa.
