Protective Effect of Basic Fibroblast Growth Factor Against Myocyte Death and Arrhythmias in Acute Myocardial Infarction in Rats

Satoru Nishida, MD; Hiroshi Nagamine, MD; Yoko Tanaka, Go Watanabe, MD

The present study in rats investigated whether basic fibroblast growth factor (bFGF) plays an important role in cardioprotection against myocardial cell death and arrhythmias in acute myocardial infarction (AMI). After ligating the left coronary artery in 62 Wistar rats, 20μg of human recombinant bFGF was injected into the infarcted myocardium in 33 rats (group F), while saline was used for 29 control rats (group C). The development of ventricular tachyarrhythmias was assessed during the first 30 min of ischemia. After 24 h occlusion, the hearts of the surviving rats (group F: n=13, group C: n=10) were excised to assess minimum infarct wall thickness and infarct size, determine the number of TUNEL-positive cardiomyocytes and to analyze Bcl-2 and Bax expression by immunohistochemical staining and Western blotting. The incidence of ventricular tachycardia was higher in group C than in group F (p<0.05). The thinning ratio was higher in group F than in group C (p<0.05). There were fewer TUNEL-positive cardiomyocytes in the infarct border area in group F than in group C (p<.0001). Western blot analysis showed greater expression of Bcl-2 in group F than in group C (p<0.05), but similar expression of Bax in the 2 groups. In conclusion, intramyocardial administration of bFGF prevented ischemia-induced myocardial cell death and arrhythmias. (Circ J 2003; 67: 334–339)

Key Words: Apoptosis; Arrhythmia; Basic fibroblast growth factor; Bcl-2

B asic fibroblast growth factor (bFGF) is a single-chain peptide with a molecular weight of 17 kD and is referred to as heparin-binding growth factor because of its affinity for heparin. bFGF induces endothelial and smooth muscle cell proliferation in vitro and angiogenesis in vivo, including the migration and proliferation of endothelial cells, vascular tube formation, and linkage to preexisting vascular networks. bFGF has been detected in the infarcted myocardial tissue of the dog and in recent years, the use of bFGF to improve blood flow and increase the vascular number in the presence of tissue ischemia has been proposed, based on the results from animal experiments. In a canine myocardial infarct model, intracoronary injection of exogenous bFGF increased the number of arterioles and capillaries in the infarcted tissue, reduced infarct size, and improved cardiac systolic function; however, the mechanism of action of bFGF in the setting of acute myocardial infarction (AMI) is unclear.

Irreversible damage occurs in acutely ischemic myocardium within 4 to 6 h and true angiogenesis can only improve blood flow over the course of days. Kajstura et al and Fliss et al have recently demonstrated that in the rat heart induces apoptosis in the ischemic myocardial cells and that this might cause late myocyte death. Necrosis and apoptosis are 2 types of cardiac cell death associated with myocardial ischemia and whether cardiac cells die of apoptosis or necrosis is critical for the development of therapeutic strategies, because apoptosis is a process that may be altered by pharmacologic interventions. bFGF has been shown to be an important survival antiapoptotic factor in a variety of cell types. Cuevas et al described the antiapoptotic effect of acidic fibroblast growth factor (aFGF) in a rat model of transient myocardial ischemia, but the antiapoptotic effects of bFGF in cardiomyocytes has not been investigated previously. We hypothesized that myocardial salvage associated with the administration of bFGF may be mediated by the prevention of myocardial apoptosis.

On the other hand, it has been shown that bFGF is localized in cardiac gap junctions which suggests a role for bFGF in the control of cardiac rhythm. The purpose of the present study was to determine the effects of intramyocardial administration of bFGF on cardiomyocyte apoptosis and cardiac arrhythmias in a rat model of AMI.

Methods

Animal Preparation

Sixty-two adult male (270–300 g) Wistar rats were anesthetized by the intraperitoneal administration of 30 mg/kg sodium pentobarbital and were mechanically ventilated using a volume respirator (Model SN-480-7, Shinano, Tokyo, Japan). The electrocardiogram was obtained with platinum needle electrodes inserted subcutaneously. The animals received humane care as outlined in the ‘The Guide for the Care and Use of Laboratory Animals’ published by the USA National Institutes of Health (NIH Publication No. 85-23, revised 1996). A left lateral thoracotomy was performed through the fourth intercostal space and AMI was induced by ligating the proximal portion of the left coronary artery. Sham-operated rats were subjected to the
identical treatment without the tying of the coronary ligation. After the coronary ligation, the rats were divided into 2 groups; Group F (n=33) received human recombinant bFGF (20 μg in 0.2 ml of saline, Kaken Pharmaceutical, Tokyo, Japan) into the ischemic myocardium using a 27 g needle, while group C (control group, n=29) received the same volume of saline in the same manner. After these procedures, the chest was closed.

Arrhythmia Assessment and Survival Rate

Ischemia-induced ventricular arrhythmias were analyzed during the first 30 min of ischemia according to the Lambeth Convention guidelines for the analysis of experimental arrhythmias. The incidence of ventricular tachycardias and ventricular fibrillation were noted. Ventricular tachycardia was defined as a run of 6 or more beats at a rate faster than resting sinus rhythm, and ventricular fibrillation was defined as a signal for which the individual QRS complex could no longer be identified.

The survival rate was recorded after 24 h occlusion. The surviving rats were anesthetized and mechanically ventilated in the same manner. After they were killed by an intravenous injection of sodium pentobarbital, the heart was excised.

Assessment of Infarct Size

The heart was transected parallel to the atroventricular groove at the center of the infarct area. The distal portion of the heart was fixed with 10% formalin for subsequent hematoxylin-eosin (H&E) staining, terminal deoxynucleotidyl transferase-mediated dUTP-biotin nick end labeling (TUNEL) and immunohistochemical staining for Bcl-2 and Bax. The proximal portion was cut into 2-mm thick slices that were incubated in 1% 2, 3, 5-triphenyl tetrazolium chloride (TTC; Sigma Chemical, St Louis, MO, USA) in phosphate buffered saline (PBS) for 10 min at room temperature, followed by fixation in 10% formalin for 60 min. The slices were then digitally scanned (GT-9600; EPSON, Tokyo, Japan) and the images were analyzed using the National Institute of Health (NIH) image program. Infarct area was identified as an area unstained by TTC and infarct size was expressed as the ratio of infarct area to the whole left ventricular area. The rest of the proximal portion of the ventricle was frozen for subsequent Western blotting of Bcl-2 and Bax (Fig 1A).

Left Ventricular Morphologic Analysis

The sections of H&E stained tissue were used to analyze left ventricular morphology. The degree of thinning of the infarcted wall was assessed by the thinning ratio, which was defined as the ratio of the minimum infarct wall thickness to normal septal wall thickness.

Detection of TUNEL-Positive Cardiomyocytes

Using paraffin sections that were 4–5μm thick, TUNEL was performed using the Apoptosis in situ Detection Kit (Wako, Osaka, Japan). Deparaffinized sections were washed with distilled water and treated with protein digestion enzyme for 5 min at 37°C. After washing with 3 changes of 0.01 mol/L PBS, sections were treated with terminal deoxynucleotidyl transferase (TdT) solution, incubated with 3% hydrogen peroxide for 5 min to block endogenous peroxidase activity, and then treated with peroxidase-conjugated antibody for 10 min at room temperature. After washing with 0.01 mol/L PBS, nick end-labeling was visualized by immersing the sections in 3,3′-diaminobenzidine solution with 0.006% hydrogen peroxide and counterstaining with hematoxylin. As a negative control, tissue sections were incubated with TdT buffer that did not contain the enzyme. As a positive control, tissue sections were treated with DNase I prior to treatment with TdT.

To assess the distribution of TUNEL-positive cardiomyocytes in the left ventricular wall, the infarcted area was divided into 4 radial segments (right lateral border area, 2 central segments, and left lateral border area). Measurement of TUNEL-positive cardiomyocytes was performed in each segment (B).

Fig1. Heart slices and myocardial segments for assessing the distribution of TUNEL-positive cardiomyocytes. Three slices of the left ventricle were used to measure the infarcted area, for H&E staining, for TUNEL staining, for immunohistochemical staining of Bcl-2 and Bax, and for western blotting of Bcl-2 and Bax (A). The infarcted area was divided into 4 radial segments (right lateral border area, 2 central segments, and left lateral border area). Measurement of TUNEL-positive cardiomyocytes was performed in each segment (B).

Immunohistochemical Staining of Bcl-2 and Bax

The immunohistochemical staining for Bcl-2 and Bax used paraffin sections that were 4–5μm thick. After the sections were deparaffinized, epitope unmasking was achieved by one of 2 methods.

Method 1 For immunohistochemical staining of Bcl-2, sections were incubated in 0.5 mg/ml of protease (p-4798, Sigma) for 30 min at room temperature. For immunohistochemical staining of Bax, sections were treated 3 times with microwave irradiation (500 W) for 5 min in 0.1 mol/L citrate buffer (pH 6.0).

Intrinsic peroxidase activity was inhibited by the addition of 3% hydrogen peroxide, and nonspecific binding

Circulation Journal Vol.67, April 2003
was blocked with normal goat serum. Rabbit polyclonal antibodies against either rat Bcl-2 (Santa Cruz, CA, USA) or rat Bax (Santa Cruz) were used as the primary antibodies, which were diluted 1:50 and incubated with the tissue sections for 45 min at room temperature. The secondary antibody, an anti-mouse/anti-rabbit labeled polymer, prepared by combining amino acid polymers with peroxidase and goat anti-mouse immunoglobulin (Ig) and anti-rabbit Ig reduced to Fab' fragments (Nichirei, Japan), was incubated with the tissue sections for 30 min at room temperature. Sections were then stained with 0.2 mg/ml of 3,3'-diaminobenzidine tetrahydrochloride for 10 min at room temperature. Between each step, the sections were washed with distilled water or 10 mmol/L sodium PBS (pH 7.2). The sections were then counterstained with hematoxylin.

Western Blot Analysis of Bcl-2 and Bax

Total protein was extracted from normal and infarcted areas of the left ventricle. Approximately 60 mg of heart tissue was placed in 300 μl lysis buffer (1% Nonidet P-40, 1% sodium deoxycholate: 0.1% sodium dodecyl sulfate [SDS] in 1×PBS), and homogenized at 4°C for 20 s, incubated on ice for 30 min, centrifuged at 15,000 G for 10 min, and the supernatant removed. Protein concentration was measured using a BioRad model 550 microplate reader. Total protein (50 μg) was mixed with loading buffer (B7709S, New England BioLabs, MA, USA), boiled for 3 min, and loaded onto a 4-12% Bis-Tris gel (NP0322 NuPAGE, Invitrogen, San Diego, CA, USA). Gels were run with a full range molecular weight ladder (Rainbow MW marker, Amersham Pharmacia, Biotech UK Ltd, Bucks, UK) and a Jurkat cell lysate (sc-2204, Santa Cruz) as a positive control sample. Proteins were transferred to an Immobilon-P membrane (IPVH 00010, Millipore, MA) by semidry blotting. Membranes were blocked with 5% milk in 1×PBS-Tween (20 mmol/L Tris HCl pH 7.6, 137 mmol/L NaCl, 0.05% Tween-20) for 1 h at room temperature. Membranes were subsequently exposed to rabbit polyclonal anti-rat Bcl-2 (Santa Cruz) or rabbit polyclonal anti-rat Bax (Santa Cruz) at 1:500 dilution in PBS-Tween for 3 h. Bound antibody was detected by horseradish peroxidase conjugated anti-rabbit IgG. Finally, enhanced chemiluminescence (ECL) detection reagents were employed to visualize the peroxidase reaction products (Amersham). Bcl-2 was detected as a 26-kDa band and Bax as a 21-kDa band. The intensities of the bands were quantified using the NIH image program. Band densities were normalized to a sham operation control sample run on all gels.

Statistical Analysis

Data are expressed as the mean ± standard error of the mean (SEM), with the exception of the percent incidence of arrhythmic events and survival rate, which were analyzed by chi-square analysis. The thinning ratio, infarct size, and Bcl-2 and Bax expressions were analyzed using an unpaired t test. Analyses of TUNEL-positive cardiomyocytes from different myocardial regions were performed using two-way ANOVA followed by Fisher's post hoc comparison. A value of p<0.05 was considered statistically significant.

Results

Arrhythmia Assessment and Survival Rate

The incidence of ventricular tachycardia was significantly higher in group C than in group F (82.8% vs 54.5%, respectively, p<0.05, Fig 2A), but the incidence of ventricular fibrillation was similar in the 2 groups (41.1% in group C and 33.3% in group F). The survival rate was 34.5% (10 of 29 rats) in group C and 39.4% (13 of 33 rats) in group F (NS, Fig 2B).
Protective Effect of bFGF in Rat AMI

Circulation Journal   Vol.67, April 2003

Left Ventricular Morphologic Analysis and Infarct Size
The left ventricular thinning ratio was significantly higher in group F than in group C (79.3±4.9% in group F \([n=13]\) and 64.5±4.1% in group C \([n=10]\), \(p<0.05\), Fig 3A). The infarct size, which is expressed as the ratio of infarct area to total left ventricular (LV) area, tended to be smaller in group F, although the difference was not statistically significant (36.6±3.6% in group C and 31.8±4.0% in group F, Fig 3B).

TUNEL-Positive Cardiomyocytes
In group C, the percentage of TUNEL-positive cardiomyocytes was similar in all areas, but in group F, the percentage of TUNEL-positive cardiomyocytes was significantly lower in the left and right lateral border areas compared with the central segment \((p<0.05\) for both). The percentage of TUNEL-positive cardiomyocytes was significantly reduced in the left and right lateral border areas in group F compared with group C (Fig 4).

Immunohistochemical Localization and Western Blot Analysis of Bcl-2 and Bax
Bcl-2-positive cardiomyocytes were observed diffusely in the LV free wall (Fig 5A), whereas Bax-positive cardiomyocytes were distributed throughout the left ventricle (Fig 5B). The distribution of Bcl-2 and Bax-positive cardiomyocytes was similar in the 2 groups. Western blot analysis for Bcl-2 and Bax expression in the LV myocardium are shown in Fig 6A. Normalized densities for the Bcl-2 signal were significantly greater in group F than in group C.
(1.01±0.18 in group C vs 1.55±0.16 in group F, p<0.05, Fig 6B), although the normalized densities for the Bax signal were similar in the 2 groups (Fig 6C).

Discussion

We recently reported that intramyocardial administration of bFGF increased regional myocardial blood flow and capillary and arteriolar density, reduced thinning of the infarcted region, and improved ventricular function in a canine myocardial infarct model but, however, in the infarct and border zone the administration of bFGF increased myocardial blood flow at 3 days and up to 1 week after AMI, respectively, which raises questions concerning the mechanism of action of bFGF in the setting of acute infarction. Specifically, irreversible damage occurs in acutely ischemic myocardium within 4 to 6 h of acute infarction, and true angiogenesis can only improve blood flow over the course of days.

The present study demonstrates that the intramyocardial administration of bFGF reduced the number of TUNEL-positive cardiomyocytes in the infarct border area and upregulated the expression of Bcl-2 in rats that underwent 24 h coronary occlusion. These results show that bFGF may prevent myocardial apoptosis triggered by acute ischemia. TUNEL detects single-strand DNA breaks as well as double-strand DNA breaks with resulting free 3'-OH termini. Therefore, TUNEL may not be specific for apoptosis, and some necrotic cells may be TUNEL-positive. However, it provides valuable information concerning the tissue distribution and cell types undergoing cell death. To evaluate the effect of bFGF on apoptosis, we performed semi-quantitative assessment of Bcl-2 and Bax expression, which are important modulators of apoptosis because Bcl-2 promotes cell survival and Bax accelerates cell death. The present study demonstrates that Bcl-2 expression is significantly greater in bFGF-treated hearts than in control hearts. The ability of bFGF to promote Bcl-2 upregulation may explain, at least in part, its beneficial effects in the infarcted myocardium. The results in our study provide the first evidence that administration of bFGF counteracts cardiomyocyte apoptosis associated with coronary occlusion.

Kondo et al have demonstrated that removing bFGF or administering anti-bFGF monoclonal antibody induces apoptosis in murine aortic endothelial cells, and that constitutive expression of Bcl-2 using gene transfer techniques decreases apoptosis induced by removing bFGF which suggests a potential bFGF–Bcl-2 interaction. Karsan et al have demonstrated that bFGF inhibits endothelial apoptosis by upregulating Bcl-2, but not Mcl-1, Bcl-XL, or Bax. Bcl-2 expression was not upregulated at early time points but bFGF had a protective effect without Bcl-2 upregulation. Therefore, bFGF inhibits endothelial cell apoptosis by Bcl-2-dependent and independent mechanism. In our study, the administration of bFGF caused overexpression of Bcl-2, but not Bax and we hypothesize that the cardioprotective effect of bFGF is related to Bcl-2 upregulation.

With respect to myocardial remodeling, it has been reported that in the rat heart there is very early remodeling of the myocardial infarct, a process that is characterized by extensive dilation of the left ventricular cavity and marked thinning of the infarcted left ventricular wall. In our study, the minimum wall thickness of the infarcted tissue was maintained by the administration of bFGF, suggesting that bFGF is effective in inhibiting early remodeling. This finding could be partially attributed to the attenuation of cardiomyocyte apoptosis; we previously reported that intramyocardial administration of bFGF reduces left ventricular remodeling with an increase in regional myocardial perfusion and angiogenesis 4 weeks after coronary occlusion in a canine model. Therefore, administration of bFGF preventing left ventricular remodeling by preventing myocardial apoptosis before angiogenesis can occur.

The infarct size, determined by TTC staining, was also reduced by the administration of bFGF, although the difference was not statistically significant. The capacity of bFGF to limit infarct size following intracoronary injection was initially reported by Yanagisawa-Miya et al and we are currently investigating the effect of bFGF on infarct size reduction in a canine model. Compared with dogs, rats have few native collaterals and it is likely that the effect of infarct size reduction is determined by the collateral blood supply and the animal species. In our study, the infarct size was determined as the ratio of infarct area to the whole left ventricular area, but if we examined the infarct size as the ratio of infarct area to the area at risk, it might be significantly reduced.

Our results show a reduction in the incidence of ischemia-induced ventricular tachycardia in bFGF-treated rats. Cuevas et al demonstrated that in a rat model of myocardial ischemia and reperfusion, the administration of aFGF just before coronary reperfusion reduced the incidence of ventricular tachycardia and ventricular fibrillation; but the anti-arrhythmic effect of bFGF has not been investigated in previous studies. Although the present study shows an anti-arrhythmic effect of bFGF, the molecular mechanisms underlying this effect remain to be investigated. It has been reported that bFGF localizes to cardiac gap junctions which is potentially a very significant observation because it suggests that bFGF exerts a regulatory influence on the intracellular communication of such junctions and therefore may regulate the coordination of contractility and cardiac rhythm. These findings suggest that the anti-arrhythmic effects of bFGF may be mediated through the cardiac gap junction channels and we hypothesize that the administration of bFGF could be a beneficial adjunctive component of anti-arrhythmic therapy in the setting of AMI.

In conclusion, intramyocardial administration of bFGF in the setting of myocardial ischemia is cardioprotective, preventing the myocardial apoptosis and ventricular tachyarrhythmias triggered by acute myocardial ischemia. Intramyocardial administration of bFGF may be a new therapeutic approach for patients with AMI.
