Background: Oxidative stress and pulmonary veins (PVs) play critical roles in the pathophysiology of atrial fibrillation. The purpose of the present study was to investigate whether oxidative stress and antioxidant agents can change the electrophysiological characteristics of the left atrium (LA) and PVs.

Methods and Results: Conventional microelectrodes were used to record the action potentials (APs) in isolated rabbit PV and LA specimens before and after H₂O₂ administration with or without ascorbic acid or N-mercaptopropionyl-glycine (N-MPG, a free radical ·OH scavenger). H₂O₂ (0.02 and 0.2 mmol/L) decreased the PV spontaneous rates from 2.0±0.1 Hz to 1.6±0.1 Hz, and 1.7±0.1 Hz (n=10, P<0.05), but H₂O₂ (2 mmol/L) increased PV spontaneous rates from 2.0±0.1 Hz to 2.8±0.2 Hz. H₂O₂ easily induced PV burst firing and early afterdepolarizations, but not in the LA. H₂O₂ shortened the AP duration and increased the contractile force to a greater extent in the LA than in PVs. In addition, the H₂O₂-induced PV burst firing and increasing spontaneous rates were suppressed or attenuated by pretreatment with ascorbic acid (1 mmol/L) or N-MPG (10 mmol/L).

Conclusions: H₂O₂ significantly changed the electrophysiological characteristics of PV and LA through activation of free radicals and may facilitate the occurrence of atrial fibrillation. (Circ J 2010; 74: 1547–1556)

Key Words: Antioxidant; Atrial fibrillation; Hydrogen peroxide; Pulmonary vein

Atrial fibrillation (AF) is the most important sustained clinical arrhythmia and can induce cardiac dysfunction, and stroke and increase mortality. Oxidative stress plays an important role in the pathophysiology of cardiovascular diseases. In addition, oxidative stress contributes to the genesis of AF. Oxidative modification of proteins was found in chronic AF patients. Moreover, it has been demonstrated that myocardial NAD(P)H oxidase significantly contributes to superoxide production in the human atrium during AF. Oxidative stress directly changes cardiac function, and stroke and increase mortality. Because the risk factors (inflammatory cytokines, stretching, and angiotensin II) for AF have all been shown to increase oxidative stress and arrhythmogenesis, oxidative stress may increase PV and atrial arrhythmogenesis. Therefore, the purpose of the present study was to evaluate the electrophysiological effects of oxidative stress on PVs and the atrium, and investigate whether antioxidant agents can alter the oxidative stress on PVs and atrial electrical activity.

Methods

Rabbit PV and Left Atrium (LA) Tissue Preparations
The investigation conformed to the institutional Guide for the Care and Use of Laboratory Animals and the Guide for the Care and Use of Laboratory Animals published by the US National Institutes of Health. As previously described, New Zealand rabbits (weighing 1.5–2.0 kg) were anesthetized with an iv injection of sodium pentobarbital (40 mg/kg). A mid-
line thoracotomy was then performed and the heart with the lungs was removed. For dissection of the PVs, the LA was opened by an incision along the mitral valve annulus extending from the coronary sinus to the septum in Tyrode’s solution with a composition of 137 mmol/L NaCl, 4 mmol/L KCl, 15 mmol/L NaHCO₃, 0.5 mmol/L NaH₂PO₄, 0.5 mmol/L MgCl₂, 2.7 mmol/L CaCl₂, and 11 mmol/L dextrose. The PVs were separated from the atrium at the level of the LA–PV junction and separated from the lungs at the ending of the PV myocardial sleeves. One end of the preparations, consisting of the PVs and LA–PV junction, was pinned with needles to the bottom of a tissue bath. The other end (distal PV) was

Oxidative Stress on Pulmonary Veins

connected to a Grass FT03C force transducer with a silk thread. The adventitia or epicardial side of the preparations faced upwards. For LA experiments, the LA appendage (approximately 10×5×0.5 mm) was isolated and prepared as described previously.

Electrophysiology and Pharmacology

The transmembrane action potential (AP) of the PVs and LA was recorded using machine-pulled glass capillary microelectrodes filled with 3 mol/L of KCl. Preparations were connected to a WPI model FD223 electrometer under a tension of 150 mg. The electrical and mechanical events were shown simultaneously on a Gould 4072 oscilloscope and Gould TA11 recorder. The signals were recorded digitally with a 16-bit accuracy at a rate of 125 kHz. Electrical stimulus with

a 10-ms duration and supra-threshold strength was provided by a Grass S88 stimulator through a Grass SIU5B stimulus isolation unit. Different concentrations of H$_2$O$_2$ (0.02, 0.2, and 2 mmol/L) were sequentially superfused to test the pharmacological responses. The preparations were treated with H$_2$O$_2$ for at least 30 min for each concentration. To evaluate the preventive and treating effects of antioxidants, ascorbic acid (1 mmol/L) or N-(mercaptopropionyl)-glycine (N-MPG, 10 mmol/L, a specific scavenger of the ·OH free radical) was treated 30 min before or 60 min after H$_2$O$_2$ administration, respectively. Verapamil (calcium channel blocker, 0.1 μmol/L) or ryanodine (ryanodine receptor blocker, 0.1 μmol/L) was administered after H$_2$O$_2$ (2 mmol/L) to elucidate the role of calcium homeostasis in H$_2$O$_2$-induced PV arrhythmogenesis. Parameters of the AP were measured with 2-Hz electrical stimuli before and after drug administration in the LA or PV without spontaneous activity, which was measured after 10 min of superfusion. The AP amplitude (APA) was obtained from the resting membrane potential (RMP) or maximum diastolic potential to the peak of AP depolarization. The AP durations at a repolarization of 20%, 50%, and 90% of the APA were measured as APD$_{90}$, APD$_{50}$, and APD$_{20}$, respectively.

Effect of H$_2$O$_2$ on Electrical Activity of PVs and LA

PV spontaneous activity (n=35, 73%) was found in 48 rabbit PV tissue preparations with a mean frequency of 2.0±0.1 Hz (cycle length, 503±19 ms). The PVs with spontaneous activity had smaller APA (101±2 mV vs 109±2 mV, P<0.001) and shorter APD$_{90}$ (89±3 ms vs 101±3 ms, P<0.05) than the PVs without spontaneous activity (n=13). The maximum diastolic potential in the PVs with spontaneous activity was less negative than the RMP in the PVs without spontaneous activity (−74.3±0.4 mV vs −79.4±1.4 mV, P<0.001). Figure 1A shows examples of the effects of H$_2$O$_2$ (0.02, 0.2, and 2 mmol/L) on the PV spontaneous activity. Compared to those of the control, H$_2$O$_2$ (0.02, and 0.2 mmol/L) reduced the PV spontaneous activity by 22±5% and 17±5%, respectively. In contrast, H$_2$O$_2$ (2 mmol/L) significantly increased PV spontaneous activity by 36±10%. Moreover, H$_2$O$_2$ (0.02, 0.2, and 2 mmol/L) induced the occurrence of PV burst firing (30%, 60%, and 100%) and early afterdepolarizations (0%, 10%, and 50%) in a dose-dependent manner (Figure 1B). H$_2$O$_2$ at 2 mmol/L induced a higher incidence of PV burst firing and early afterdepolarizations than those at baseline or after the administration of H$_2$O$_2$ at 0.02 mmol/L.

In PVs without spontaneous activity (Figure 2), H$_2$O$_2$ (0.02, 0.2, and 2 mmol/L) concentration-dependently shortened the APD$_{90}$, APD$_{50}$ and APD$_{20}$, but H$_2$O$_2$ did not change the RMP or APA. H$_2$O$_2$ at 2 mmol/L initially prolonged the AP duration, and then shortened the AP duration during the initial administration of 15 min. Compared to those in the control, H$_2$O$_2$ (2 mmol/L) significantly increased PV contractility. Moreover, as in the examples shown in Figure 2C, H$_2$O$_2$ (0.02, 0.2, and 2 mmol/L) easily induced the occurrence of PV burst firing (75%, 87%, and 100%) and early afterdepolarizations (38%, 38%, and 62%). H$_2$O$_2$ (2 mmol/L) administration also produced a longer PV burst firing (13±3 s vs 1±1 s, P<0.005) than did H$_2$O$_2$ at 0.02 mmol/L.

In LA tissue (Figure 3), H$_2$O$_2$ (0.02, 0.2, and 2 mmol/L) concentration-dependently shortened the APD$_{90}$, APD$_{50}$ and APD$_{20}$, but H$_2$O$_2$ did not change the RMP or APA. H$_2$O$_2$ at 2 mmol/L initially prolonged the AP duration, and then shortened the AP duration during the initial administration of 15 min. Compared to those in the control, H$_2$O$_2$ (2 mmol/L) significantly increased PV contractility. Moreover, as in the examples shown in Figure 3C, H$_2$O$_2$ (0.02, 0.2, and 2 mmol/L) easily induced the occurrence of PV burst firing (75%, 87%, and 100%) and early afterdepolarizations (38%, 38%, and 62%). H$_2$O$_2$ (2 mmol/L) administration also produced a longer PV burst firing (13±3 s vs 1±1 s, P<0.005) than did H$_2$O$_2$ at 0.02 mmol/L.

Results

The maximum upstroke velocity was acquired using the maximum positive value of the first derivative of the AP. Spontaneous activity was defined as the constant occurrence of spontaneous APs in the absence of any electrical stimuli. Burst firing was defined as the occurrence of accelerated spontaneous potential (faster than the basal rate) with sudden onset and termination.

Statistical Analysis

All continuous variables are expressed as mean±SEM. A repeated-measures ANOVA with a post-hoc LSD, or paired t-test was used to compare differences before and after drug administration. Unpaired t-test was used to compare the effects of H$_2$O$_2$ in the absence and presence of ascorbic acid or N-MPG, and the differences between PVs and LA. P<0.05 was considered statistically significant.
and APD_{20}. Similar to those in PVs, H\textsubscript{2}O\textsubscript{2} at 2 mmol/L initially prolonged the AP duration, and then shortened the AP duration. Moreover, compared to those in the control, H\textsubscript{2}O\textsubscript{2} (2 mmol/L) significantly increased LA contractility. Different from that in PVs without spontaneous activity, however, H\textsubscript{2}O\textsubscript{2} (0.02, 0.2, and 2 mmol/L) did not induce burst firing, but occasionally induced triggered beats (10%, 10%, and 60%) or early afterdepolarizations (0%, 10%, and 10%). Moreover, H\textsubscript{2}O\textsubscript{2} (0.2, and 2 mmol/L) shortened the APD\textsubscript{90} (42±3% vs 20±3%, P<0.005; and 45±3% vs 23±3%, P<0.005) or APD\textsubscript{50} (51±4% vs 26±4%, P<0.005; and 58±3% vs 32±6%, P<0.005) in the LA to a greater extent than in the PVs. In addition, H\textsubscript{2}O\textsubscript{2} (2 mmol/L) increased the contractile force in the LA to a greater extent as compared to that in the PVs without spontaneous activity (101±22% vs 42±6%, P<0.05). In order to study whether enhanced transient outward currents might contribute to the H\textsubscript{2}O\textsubscript{2}-induced AP duration shortening, we administered a blocker of transient outward currents (4-aminopyridine, 2 mmol/L) in the LA and found that 4-aminopyridine can reverse the H\textsubscript{2}O\textsubscript{2}-induced shortening of APD\textsubscript{90}, APD\textsubscript{50}, and APD\textsubscript{20} (Figure 4).
Oxidative Stress on Pulmonary Veins

Figure 6. Effects of ascorbic acid and N-mercapto-propionyl-glycine (N-MPG) on H$_2$O$_2$-induced pulmonary vein (PV) arrhythmogenesis. (A) Ascorbic acid and (B) N-MPG abolished H$_2$O$_2$-induced PV spontaneous activity. These effects were reversible after washout of ascorbic acid or N-MPG (Lower panel).

Figure 7. Effects of verapamil or ryanodine on H$_2$O$_2$-induced pulmonary vein (PV) spontaneous activity. Verapamil (0.1 μmol/L, n=6) or ryanodine (0.1 μmol/L, n=6) decreased H$_2$O$_2$-induced PV spontaneous activity. *P<0.05, **P<0.01, ***P<0.005 vs baseline.
Effects of Ascorbic Acid and N-MPG on H\textsubscript{2}O\textsubscript{2}-Induced PV and LA Arrhythmogenesis

**Figure 5A** shows the effects of ascorbic acid on PV spontaneous activity. Ascorbic acid (1 mmol/L) mildly decreased the PV spontaneous activity from 2.3±0.2 Hz to 2.1±0.1 Hz (n=9; P<0.05). In the presence of ascorbic acid (1 mmol/L), however, H\textsubscript{2}O\textsubscript{2} (0.02, 0.2, and 2 mmol/L) decreased the PV spontaneous activity by 9±4%, 8±4% and 13±4%, respectively, and that effect was reversed after washout. The effects of H\textsubscript{2}O\textsubscript{2} (0.02, and 2 mmol/L) on PV spontaneous activity significantly differed between those in the presence and absence of ascorbic acid. In the presence of ascorbic acid (1 mmol/L), H\textsubscript{2}O\textsubscript{2} (0.02, 0.2, and 2 mmol/L) occasionally induced PV burst firing (0%, 33%, and 33%) and early afterdepolarizations (0%, 0%, and 11%). Compared to that without ascorbic acid, H\textsubscript{2}O\textsubscript{2} (2 mmol/L) in the presence of ascorbic acid produced a lower incidence of PV burst firing (33% vs 100%, P<0.01).

N-MPG (10 mmol/L) decreased the PV spontaneous activity from 2.0±0.1 Hz to 1.3±0.1 Hz (n=6; P<0.05; **Figure 5B**). In the presence of N-MPG (10 mmol/L), however, H\textsubscript{2}O\textsubscript{2} (0.02, 0.2, and 2 mmol/L) decreased PV spontaneous activity by 16±4%, 16±5%, 19±8%, respectively, in a non-concentration dependent manner, and this effect was reversed after washout. Similar to that in the presence of ascorbic acid, in the presence of N-MPG, H\textsubscript{2}O\textsubscript{2} (0.02, 0.2, and 2 mmol/L)
occasionally induced PV burst firing (17%, 17%, and 33%) and early afterdepolarizations (0%, 16%, and 16%). Compared to that in the absence of N-MPG, H$_2$O$_2$ (2 mmol/L) in the presence of N-MPG produced a lower incidence of PV burst firing.

Figure 6 shows examples of the effects of ascorbic acid (1 mmol/L) and N-MPG (10 mmol/L) on H$_2$O$_2$ (2 mmol/L)-induced PV spontaneous activity. Ascorbic acid (1 mmol/L) reduced the H$_2$O$_2$-induced PV spontaneous activity from 3.7±0.3 Hz to 1.9±0.1 Hz (n=7, P<0.05) and abolished the occurrence of PV burst firing. Similarly, N-MPG (10 mmol/L) also reduced H$_2$O$_2$-induced PV spontaneous activity from 3.6±0.1 Hz to 1.3±0.3 Hz (n=5, P<0.05), and abolished PV burst firing. Both of those effects were reversible after washout (Figure 6). As the example shown in Figure 7A, verapamil (0.1 μmol/L) significantly decreased the H$_2$O$_2$ (2 mmol/L)-induced PV spontaneous activity. Similarly, ryanodine (0.1 μmol/L) also reduced H$_2$O$_2$ (2 mmol/L)-induced PV spontaneous activity (Figure 7B).

In PVs without spontaneous activity, ascorbic acid (1 mmol/L) shortened the APD$_{90}$ and APD$_{99}$, but not the APD$_{20}$, RMP, APA or contractility (Figure 8). In the presence of ascorbic acid (1 mmol/L), however, H$_2$O$_2$ shortened only the APD$_{90}$ and reduced contractility at a concentration of 2 mmol/L. H$_2$O$_2$ (0.02, 0.2, and 2 mmol/L) had no significant effects on the APD$_{20}$, RMP, APA, or APD$_{99}$.

**Discussion**

Oxidative stress plays a vital role in the pathophysiology of a wide range of cardiovascular diseases including AF.\(^{7-10,28}\) Oxidative stress may mediate the pathological process of heart failure, inflammation, ischemia, and renin–angiotensin or sympathetic–adrenergic activations,\(^ {28}\) which are known to enhance the occurrence of AF. In the present study we found that H$_2$O$_2$ at 2 mmol/L significantly increased the rate of PV ectopic beats. In addition, H$_2$O$_2$ concentration-dependently induced or prolonged the occurrence of PV burst firing. Because the electrophysiological characteristics of PV burst firing are similar to those in clinical focal AF or atrial tachycardia, these findings strongly suggest that oxidative stress has a direct arrhythmogenic effect on PVs. Previous studies showed that oxidative stress can induce Ca$^{2+}$ overload by changing the Ca$^{2+}$ regulatory proteins or cell membrane lipid oxidation status.\(^ {28}\) In addition, H$_2$O$_2$ also enhances Ca$^{2+}$ release through increasing the opening probability of ryanodine receptors.\(^ {29}\) Taken together, these effects may contribute to the arrhythmogenic activity of H$_2$O$_2$. Because PVs have abnormal Ca$^{2+}$ homeostasis and a less negative RMP,\(^ {20,21,30-33}\) the increase in intracellular Ca$^{2+}$ and Ca$^{2+}$ release could easily induce the occurrence of PV burst firing and genesis of early afterdepolarizations. The present results show that H$_2$O$_2$-induced PV spontaneous activity could be reduced by verapamil and ryanodine. These findings collectively imply that intracellular Ca$^{2+}$ overload may contribute to H$_2$O$_2$-induced PV arrhythmogenesis and also indicate a high susceptibility to oxidative stress in PVs as compared to the LA. Taken together, it is reasonable to assume that oxidative stress has a high arrhythmogenic potential for inducing AF by enhancing PV electrical activity. Previous studies, however, have indicated that clinically relevant ranges of H$_2$O$_2$ were expected to have a magnitude of μmol/L. Therefore, the concentration (2 mmol/L) of H$_2$O$_2$ used in the present study may be supra-physiological. Additionally, the increases in intracellular Ca$^{2+}$ and Ca$^{2+}$ release by H$_2$O$_2$ may also enhance the contractility of PVs and LA as we found. Because PV cardiomyocytes contain pacemaker currents,\(^ {20-22}\) the known inhibitory effects of H$_2$O$_2$ on the pacemaker currents may contribute to a slowing of the PV spontaneous activity during the administration of low concentrations (0.2, and 0.02 mmol/L) of H$_2$O$_2$.\(^ {34}\)

Differing from that in ventricular myocytes,\(^ {35}\) H$_2$O$_2$ can shorten the AP duration in PVs and LA. Because transient outward currents contribute more to the AP duration in PVs and LA cardiomyocytes than in ventricular myocytes, the shortening of AP duration by H$_2$O$_2$ was proposed to arise from its known effect on increasing transient outward currents.\(^ {36}\) The present finding that 4-aminopyridine could reverse the H$_2$O$_2$-induced shortening of AP duration in LA also suggests this mechanism. Moreover, H$_2$O$_2$ shortened the AP duration to a greater extent in LA than in PVs. This effect can increase dispersion of AP duration to enhance the genesis of reentry circuit. Additionally, oxidative stress may induce anatomical changes and atrial fibrosis,\(^ {37}\) which can decrease conduction velocity and contribute to the maintenance of AF.\(^ {38,39}\)

Antioxidant agents have been shown to have an antiarrhythmic potential. A previous study showed that ascorbic acid can reduce the occurrence of postoperative AF and attenuate the electrical remodeling from rapid atrial pacing.\(^ {41}\) It is not clear, however, whether antioxidant agents can reduce the occurrence of AF though decreasing PV arrhythmogenesis. In the present study we found that ascorbic acid has direct electrophysiological effects on PVs with the decrease of spontaneous activity and shortening of APD$_{90}$ and APD$_{99}$. Moreover, ascorbic acid and N-MPG significantly attenuated the arrhythmogenic effects of H$_2$O$_2$. Through the scavenging of reactive oxidative stresses to ameliorate the Ca$^{2+}$ overload, both ascorbic acid and N-MPG reduced H$_2$O$_2$-induced PV burst firing and genesis of early afterdepolarizations. Therefore, antioxidant agents are effective in preventing the arrhythmogenesis induced by oxidative stress in PVs. Furthermore, during H$_2$O$_2$-induced PV arrhythmogenesis, the administration of N-MPG or ascorbic acid not only reduced the PV spontaneous activity but also abolished the PV burst firing. These results indicate that acute administration of antioxidant agents can reverse arrhythmogenesis due to oxidative stress. Therefore, antioxidant agents should be a promising antiarrhythmic therapy in AF enhanced by oxidative stress such as heart failure, sepsis or activation of the renin–angiotensin, and adrenal systems. Previous reports, however, have found that antioxidants such as β-carotene, vitamin C or E produced little or controversial clinical benefit,\(^ {13,25}\) despite the beneficial effects of antioxidants shown in in vitro or animal studies in the field of atherosclerosis.\(^ {6}\) The possible dissociation between in vivo and in vitro studies should be taken into consideration. Further clinical study is warranted to confirm the antioxidant effect on the prevention of AF.

**Conclusions**

The present study has demonstrated that H$_2$O$_2$ significantly changes the electrophysiological characteristics of PV and LA through activation of free radicals and may facilitate the occurrence of AF.
