Balloon pulmonary angioplasty (BPA) is a novel method of treating inoperable or persistent CTEPH. It has been shown to improve hemodynamic, echocardiographic, biochemical and functional parameters in patients with inoperable CTEPH,9–17 but the effect of BPA on QoL has never been studied before.

**Methods and Results:** Twenty-five patients with inoperable or persistent CTEPH were enrolled in the study and filled out the 36-item Short Form (SF-36v2) questionnaire twice: prior to commencement of BPA treatment and after ≥3 BPA sessions. In addition WHO functional class, distance on the 6-min walk test (6MWT) and hemodynamic parameters such as right atrial pressure (RAP), mean pulmonary artery pressure (mPAP), cardiac index (CI) and pulmonary vascular resistance (PVR) were assessed. QoL improved significantly in all domains, except for physical pain. Improvement in RAP (10.5±3.4 vs. 6.2±2.2 mmHg; P<0.05), mPAP (51.7±10.6 vs. 35.0±9.1 mmHg; P<0.05), CI (2.2±0.5 vs. 2.5±0.4 L/min · m²; P=0.04), PVR (10.4±3.9 vs. 5.5±2.2 Wood units; P<0.05), functional class (96% vs. 20% in WHO class III and IV, P<0.05) and improvement in 6MWT distance (323±135 vs. 410±109 m; P<0.05) was observed. The only significant correlation was between the mental component summary score of QoL after completion of treatment and percentage improvement in the 6MWT (−0.404, P<0.05).

**Conclusions:** Alongside improvement in functional and hemodynamic parameters, BPA also provides significant improvement in QoL.

**Key Words:** Balloon pulmonary angioplasty; Chronic thromboembolic pulmonary hypertension; Quality of life

Chronic thromboembolic pulmonary hypertension (CTEPH) is a rare but dangerous disease caused by the presence of chronic thrombi in pulmonary arteries. The gold standard in the treatment of CTEPH is a surgical procedure: pulmonary endarterectomy (PEA), which significantly improves the prognosis in this group of patients.12 Additionally, after successful PEA significant reduction of symptoms as well as improvement in walk test distance, hemodynamic parameters, quality of life (QoL) and exercise capacity have been observed.3–7 Unfortunately, despite constant improvements in surgical technique, approximately 50% of patients with CTEPH do not qualify for surgical treatment, mainly due to a peripheral location of thrombi in the pulmonary bed. In approximately 16–30% of operated patients, PH persists despite PEA.8

Chronic thromboembolic pulmonary hypertension (CTEPH) is a rare but dangerous disease caused by the presence of chronic thrombi in pulmonary arteries. The gold standard in the treatment of CTEPH is a surgical procedure: pulmonary endarterectomy (PEA), which significantly improves the prognosis in this group of patients.12 Additionally, after successful PEA significant reduction of symptoms as well as improvement in walk test distance, hemodynamic parameters, quality of life (QoL) and exercise capacity have been observed.3–7 Unfortunately, despite constant improvements in surgical technique, approximately 50% of patients with CTEPH do not qualify for surgical treatment, mainly due to a peripheral location of thrombi in the pulmonary bed. In approximately 16–30% of operated patients, PH persists despite PEA.8

**Subjects**
All patients included in the study had a diagnosis of CTEPH established on the basis of typical post-embolic changes in
pulmonary arteries on diagnostic imaging (computed tomography angiography or perfusion lung scintigraphy, classic lung angiography) and signs of precapillary PH identified during right heart catheterization (RHC) persisting despite at least 3 months of anti-thrombotic therapy. The choice of treatment was assessed by a multidisciplinary CTEPH-team consisting of a cardiac surgeon with experience in PEA (A.B.), an interventional cardiologist with experience in BPA (M.K.) and a cardiologist experienced in using specific treatment (A.T.) for pulmonary arterial hypertension (PAH). Qualification for BPA required consensus of the 3 specialists.

All patients included in the study underwent non-invasive and invasive examinations prior to BPA. The same examinations were repeated 3–6 months after the last BPA session.

RHC
A Swan-Ganz catheter was used to measure right atrial pressure (RAP), pulmonary artery pressure (PAP) and pulmonary capillary wedge pressure (PCWP). Cardiac output (CO) was measured using thermodilution technique. Pulmonary vascular resistance (PVR) and cardiac index (CI) were calculated according to the accepted standards. In each patient, mean PAP (mPAP) >25 mmHg and PCWP ≤15 mmHg was confirmed.18

QoL and Exercise Capacity
For the purposes of this study, a license number QM036623 was obtained for using the 36-item Short Form (SF-36v2) QoL questionnaire. Prior to BPA and after completion, each patient was asked to fill out the SF-36v2 questionnaire, Polish language version. At the same time the physician attending a given patient evaluated exercise capacity according to the score developed by the World Health Organization (WHO). The data obtained from the SF-36v2 questionnaires were collected and analyzed using Certified Scoring Software 5.0™ (OPTUM, Eden Prairie, MN, USA). QoL was evaluated on 8 scales: physical functioning (PF), role-physical (RP), bodily pain (BP), general health (GH), vitality (VT), social functioning (SF), role-emotional (RE) and mental health (MH). The appropriate scales combined into groups summarize 4 parameters for evaluating the physical sphere (physical component summary, PCS) and 4 parameters for evaluating the mental sphere (mental component summary, MCS); PCS=PF+RP+VT+GH; and MCS=VT+SF+RE+MH.

For a normalized score of 1–100, the mean established in each domain was 50 points with an SD of 10 points. This standard has been established on the basis of a study of the healthy American population that was carried out in 1998. All patients underwent 6-min walk test (6MWT) prior to initiation of BPA treatment and after at least 3 BPA sessions.

BPA
The BPA was performed by 2 interventional cardiologists (M.K., A.P.) and an interventional radiologist (R.P.) experienced in coronary intervention, RHC and procedures on peripheral vessels. All patients undergoing BPA received a consent form and patient information sheet regarding the nature of the procedure and possible complications. The study protocol was approved by the Bioethics Committee at the Medical Center of Postgraduate Education.

The BPA was normally carried out using access through the right femoral vein, with unfractionated heparin given at a dose of 1–2,000 units/h. Chronic anti-thrombotic treatment with vitamin K antagonists (VKA) or new oral anticoagulants (NOAC) was discontinued at least 24 h before the procedure. During the procedure, patients on long-term oxygen treatment, received it at the same constant flow rate. An MPD, JR 4 or AL1 6-F guiding catheter (Launcher; Meditronic, Minneapolis, MN, USA) was inserted into the right or left pulmonary artery using a 90-cm 6-F vascular sheath (Flexor; Cook, Bloomington, IN, USA). In the initial phase of the study, peripheral guidewires (V-14 and V-18 Controlwire; Boston Scientific, Natick, MA, USA) were used, which were later replaced with 0.014-in guidewires (Cruiser; Biotronik, Bülach, Switzerland; Whisper MS; Abbott Vascular, Santa Clara, CA, USA). Semicompliant balloon catheters with a size between 1.25 mm and 10 mm (Pantera, Biotronik; Passeo, Biotronik) were used. The balloon width and length was adjusted to the type of the lesion and degree of stenosis of the pulmonary artery on angiography. After inflation,
contrast agent was injected into the treated vessel in order to evaluate the angiographic effect of the procedure: analysis of flow across the treated lesion, peripheral parenchymal perfusion and venous return from the revascularized segment (Figure 1). Final angiography was also carried out in order to rule out possible injury to the vessel. In special cases in which there were doubts about the nature or significance of a lesion, additional diagnostic tools were used such as intravascular ultrasound or evaluation of the pressure gradient across the evaluated lesion using a pressure wire. After completion of the procedure, each patient was transferred to the cardiac intensive care unit in order to monitor vital functions and potential complications within 48 h.

Statistical Analysis
Categorical variables are presented as count (percentage), and continuous variables as mean±SD. Student’s t-test was used for comparison of data before and after BPA for continuous variables, and chi-squared test for categorical variables. Spearman correlation was used to test for association between QoL indices and change in hemodynamic variables after BPA. P<0.05 was considered statistically significant. All statistical analysis was performed using STATISTICA 10 (STATSOFT, Tulsa, OK, USA).

Results
Twenty-five patients with CTEPH hospitalized in the Department of Pulmonary Circulation and Thromboembolic Diseases of the European Health Center, Poland were included in the study (Table 1). In this group, 22 patients (88%) had inoperable CTEPH, mainly due to a distal location of thrombi (n=18; 72%), or contraindications for surgery due to comorbidities and a high periprocedural risk (n=4; 16%). Additionally 3 patients (12%) were diagnosed with persistent PH despite previous PEA, and BPA was carried out as a complementary treatment. All patients underwent at least 3 BPA sessions or completed BPA treatment due to satisfactory clinical effect.

In the study group, 96 BPA sessions (mean, 3.8±1.3 per patient) were carried out. In total, 447 pulmonary vessels (mean, 17.8±11.5 per patient) were treated. The most frequent complication observed during BPA was desaturation, which usually resolved within 24–48 h of oxygen therapy. Mild hemoptysis (<50 mL/24 h) was observed during 5 BPA sessions (5.2%). None of the patients required non-invasive positive pressure ventilation. Intubation was not necessary. In 4 cases (4.1%) the pulmonary artery was injured by the guidewire, in 2 cases emergency balloon inflation in the injured vessel was performed, and 1 injured vessel underwent embolization.

Compared with baseline, mPAP and mean RAP were significantly reduced after a series of BPA, from 51.7±10.6 to 35.0±9.1 mmHg (P<0.01) and from 10.5±3.4 to 6.2±2.2 mmHg (P<0.01), respectively. An increase in CI (from 2.2±0.5 to 2.5±0.4 L/min·m 2, P<0.05) was observed, and PVR decreased on average by 47%; from 10.4±3.9 to 5.5±2.2 Wood units (P<0.01). PCWP remained unchanged.

Figure 2 presents the baseline and follow-up hemodynamics. A significant increase in 6MWT distance (323±135 vs. 410±109 m; P<0.001) was also observed. Prior to BPA, 96% of patients had symptoms of WHO functional class III and IV. The percentage of patients in class III and IV decreased to 20% after at least 3 BPA sessions (P<0.05).

At baseline evaluation using the SF-36v2 questionnaire, 64% of respondents described their general health status as unsatisfactory, and 44% stated that they felt somewhat worse than 1 year ago. After completing BPA treatment, 44% of patients described their general health status as good, and 80% felt a significant improvement compared with the previous year (P<0.05; Table 2).

Baseline QoL in the CTEPH patients was significantly worse compared with the healthy population. After a series of BPA, a significant improvement was observed in QoL on all the scales and on scales normalized relative to the healthy population, except for pain experience (Table 3). Both PCS and MCS spheres underwent significant
improvement after a series of BPA (Table 3). Transformation of the scores into a 0–100 scale and comparison with the healthy population are presented in Figures 3, 4. No significant correlation between the number of pulmonary vessels treated and improvement in MCS (r=−0.083; P=0.703) and in PCS (r=−0.113; P=0.589) was found. Also, no significant correlation between the number of BPA sessions and improvement in MCS (r=0.098; P=0.641) or in PCS (r=−0.185; P=0.376) was seen. Reduction in PVR after a series of BPA did not correlate with improvement in PCS (r=−0.004; P=0.984) or in MCS (r=0.116; P=0.58). Similarly, decrease in mPAP after a series of BPA did not correlate with improvement in MCS (r=0.285; P=0.166) or in PCS (r=0.164; P=0.434). Improvement in CO did not correlate with improvement in MCS (r=0.047; P=0.822) or in PCS (r=0.011; P=0.956). Functional improvement observed on 6MWT correlated only with MCS (r=−0.404; P<0.05) evaluated after treatment completion. Correlations between particular QoL domains evaluated after treatment completion and the number of procedures, number of vessels with restored patency, reduction in mPAP, improvement in CO, reduction in PVR and improvement in the 6MWT are listed in Table 4.

**Discussion**

Balloon angioplasty seems to be a very promising method of treating inoperable CTEPH and persistent CTEPH despite surgical treatment. Its beneficial effect on hemodynamic, biochemical, echocardiographic and functional parameters has been convincingly demonstrated. The hemodynamic and functional efficacy of BPA was also confirmed in the present study. The main goal, however, was to investigate whether BPA may also influence QoL in CTEPH. The evaluation of QoL in CTEPH patients may be a very useful tool, facilitating analysis of everyday physical functioning, determination of limitations in the performance of roles, definition of general health and vitality, and evaluation of mental health quality.

Currently, there are many QoL questionnaires developed and available for use, but there is no such questionnaire designed specifically for CTEPH patients. From among various tools used to evaluate QoL, the SF-36v2 questionnaire was chosen due to its widespread use, including in the evaluation of QoL in PH. The SF-36v2 was used for a group of 62 Finnish patients with various forms of PH who received pharmacological therapy specific for PAH. In that group, 21 patients had...
inoperable CTEPH. All subjects had a significantly lower QoL, except for the MH domain and the mental sphere (MCS), compared with the general population. Decreased QoL was also found in the present cohort of 25 CTEPH patients prior to the first BPA session.

The effect on QOL in CTEPH has so far been evaluated only for 2 treatment methods, that is, PEA and pharmacological therapy with specific drugs targeted to small pulmonary arteries. The SF-36 questionnaire was used in 308 patients with CTEPH who underwent pulmonary endarterectomy. Significant improvement after surgical treatment was found within all QoL domains, except for the emotional domain (RE). In another analysis, QoL was evaluated using the SF-36 questionnaire in 83 patients with CTEPH who were treated surgically or pharmaceutically. A significant improvement was seen in the domain of PF (P<0.01), RP (P<0.05), VT (P<0.05), SF (P<0.05) and the MH (P<0.01) in the PEA group, despite persistence of PH in some cases. Inoperable patients treated medically had improvement in QoL only in 2 domains: RP (P<0.05) and VT (P<0.05). In patients with significant hemodynamic improvement after PEA, resulting in a decrease in PVR >50% compared with baseline, a significantly improved QoL was found within the domain of PF (P<0.01), RP (P<0.045), GH (P<0.019), SF (P<0.017), RE (P<0.01) and MH (P<0.03). No improvement in QoL was found in patients with decrease in PVR after PEA <50%.

In the present study the mean reduction in PVR was approximately 47% and there was no significant correlation between any QoL domain and decrease in PVR. This could have been due to the smaller range of changes of PVR than for example in the CHEST-2 study. Nevertheless, a significant improvement in QoL was also found in operable patients with persistent CTEPH after surgery. Inoperable patients treated medically had improvement in QoL only in 2 domains: RP (P<0.05) and VT (P<0.05). In patients with significant hemodynamic improvement after PEA, resulting in a decrease in PVR >50% compared with baseline, a significantly improved QoL was found within the domain of PF (P<0.01), RP (P<0.045), GH (P<0.019), SF (P<0.017), RE (P<0.01) and MH (P<0.03). No improvement in QoL was found in patients with decrease in PVR after PEA <50%.

improvement in 6MWT distance. This shows that QoL may be an independent indicator of effectiveness of BPA. Objectively evaluated improvement in QoL may be an additional aim of BPA treatment, especially in elderly patients and those with comorbidities associated with shortened life expectancy.

Grants

This study was carried out with support of funds from the statutory activity of the Medical Center for Postgraduate Education in Warsaw.
