Background: The efficacy of exercise training (ET) programs and its relationship with long-term clinical outcomes in advanced heart failure (HF) patients with high levels of B-type natriuretic peptide (BNP) remain uncertain.

Methods and Results: We studied 340 consecutive HF patients with ejection fraction (EF) <45% who completed a 3-month ET program. Patients with BNP ≥200 pg/mL (High-BNP, n=170) had more advanced HF characteristics, including lower EF (25.0±8.6% vs. 28.1±8.0%, P=0.0008), than those with BNP <200 pg/mL. In the High-BNP patients, peak oxygen uptake (VO₂) was significantly increased by 8.3±16.2% during the ET program, and changes in peak VO₂ inversely correlated with changes in BNP (R=−0.453, P<0.0001) and changes in ventilatory efficiency (VE/VCO₂ slope) (R=−0.439, P<0.0001). During a median follow-up of 46 months, patients in the upper tertile of changes in peak VO₂ (≥13.0%), compared with those in the lower tertile (<1.0%), had lower rates of the composite of all-cause death or HF hospitalization (37.9% vs. 54.4%, P=0.036) and all-cause death (8.6% vs. 24.6%, P=0.056).

Conclusions: Even among advanced HF patients with high BNP level, an ET program significantly improved exercise capacity, and a greater improvement in exercise capacity was associated with greater decreases in BNP level and VE/VCO₂ slope and more favorable long-term clinical outcomes.

Key Words: Exercise capacity; Exercise training; Heart failure; Natriuretic peptides; Oxygen uptake

Heart failure (HF) is a major public health problem with high morbidity and mortality. Despite recent advances in pharmacological and non-pharmacological treatments, the prognosis in patients with HF remains poor.¹² In HF patients, exercise capacity, as measured by peak oxygen uptake (VO₂), is an established strong prognostic predictor,³ and an increase over time in exercise capacity has been shown to be associated with a favorable clinical outcome.⁴⁵ Exercise training (ET) improves exercise capacity in HF patients,⁶⁹ and is recommended by current HF practice guidelines at a Class I level.¹⁸¹¹ However, the association between baseline patient characteristics and the efficacy of ET programs has not been fully elucidated.

The plasma B-type natriuretic peptide (BNP) level is a reliable and established prognostic marker, and HF patients with a high BNP level have a poor prognosis.¹²¹³ In such advanced HF patients, it remains uncertain whether an ET program can safely improve exercise capacity or whether an improvement in exercise capacity by ET program will lead to favorable long-term clinical outcomes. The purpose of the present study was to evaluate the efficacy of an ET program and its relationship with long-term clinical outcomes in advanced HF patients with high BNP level (≥200 pg/mL) and receiving current optimal medical therapy.

Methods

Study Population
Consecutive HF patients who participated in a 3-month ET program between January 2002 and October 2015 at our institution were screened retrospectively. HF patients were eligible for the ET program if they met any of 3 criteria (left ventricular ejection fraction [LVEF] ≤40%, percent-predicted peak VO₂ ≤80%, and BNP level ≥80 pg/mL), and were referred to the program at their physicians’ discretion. We included patients who completed the ET pro-
program and underwent cardiopulmonary exercise testing (CPX) at the beginning and end of the program. Patients were excluded from the study if they had LVEF ≥45%, serum creatinine >2.5 mg/dL, a history of a myocardial infarction (MI) within the previous 3 months, or significant pulmonary, cerebrovascular, or orthopedic disease. Among 455 consecutive patients who entered the 3-month ET program during the study period, 6 patients were hospitalized for worsening HF without any apparent relationship to ET during the 3-month program, and 109 did not undergo the 3-month CPX mostly for social reasons such as remote residence or lack of time. Therefore, we studied 340 patients who completed the 3-month ET program with CPX data at both the beginning and the end. The presence of ischemic heart disease was shown by coronary angiography or documentation of a MI. Treatment for HF was tailored to all patients on the basis of current guidelines and was kept constant throughout the study period. The study complied with the Declaration of Helsinki, was approved by the institutional ethics committee, and all patients gave written informed consent.

ET Program
At a clinically stable stage after treatment with appropriate medications, the 3-month ET program was started with supervised in-hospital sessions consisting of walking, bicycle ergometer, and low-intensity resistance training for 20–40 min per session 3–5 times per week, followed by home ET combined with once or twice per week supervised in-hospital ET sessions, as previously described. The duration of the exercise was increased to 30–60 min, and the intensity of the endurance exercise was determined individually at a heart rate corresponding to 40–60% of heart rate reserve (maximal heart rate minus resting heart rate) or anaerobic threshold level obtained in baseline CPX, or at level 12–13 (‘a little hard’) of the 6–20 scale perceived rating of exercise (original Borg’s scale). After completing the 3-month ET program, all patients were encouraged to continue home ET with an individualized exercise prescription on the basis of the CPX result at 3 months.

Cardiopulmonary Exercise Testing
Symptom-limited CPX was performed using a cycle ergometer with respiratory gas exchange analysis at the beginning and the end of the 3-month ET program. The test consisted of an initial 2 min of rest, 1 min of warm-up (0 W load), and full exercise by an individualized ramp protocol with increments of 10–15 W/min. Expired gas analysis was performed throughout CPX on a breath-by-breath basis and the minute ventilation (VE), VO2, and carbon dioxide production (VCO2) data were stored in a computer hard disk every 6 s for off-line analysis. Based on the findings previously described, all subjects undergoing CPX had been strongly encouraged to exercise towards exhaustion with a target peak respiratory exchange ratio

| Table 1. Baseline Characteristics According to Level of B-Type Natriuretic Peptide |
|---------------------------------|----------------|----------------|----------------|----------------|
| Characteristic                  | All patients (n=340) | BNP <200 pg/mL (n=170) | BNP ≥200 pg/mL (n=170) | P value* |

Variables are expressed as mean±SD or n (%). *For comparison of BNP <200 pg/mL vs. BNP ≥200 pg/mL. ACEI, angiotensin-converting-enzyme inhibitor; AF, atrial fibrillation or flutter; ARB, angiotensin-receptor blocker; BMI, body mass index (weight in kilograms divided by the square of the height in meters); BNP, B-type natriuretic peptide; CPX, cardiopulmonary exercise testing; IHD, ischemic heart disease; LAD, left atrial diameter; LVDd, left ventricular end-diastolic diameter; LVDs, left ventricular end-systolic diameter; LVEF, left ventricular ejection fraction; RER, respiratory exchange ratio; VCO2, carbon dioxide production; VE, minute ventilation; VO2, oxygen uptake.
Exercise Training in HF With High BNP Level

phys. LVEF was measured by echocardiography, radionuclide ventriculography, cardiac magnetic resonance, or LV angiography. In all patients, blood samples were drawn for serum creatinine, hemoglobin, and BNP measurements within 3 days of baseline and 3-month CPX. Plasma BNP concentrations were measured by radioimmunoassay (Shionoria BNP kit; Shionogi & Co. Ltd., Osaka, Japan), and the change in BNP level was determined as the percentage change in the value from baseline to 3 months.

Endpoints
Follow-up data were determined from outpatient medical records, and at least 1 year of follow-up was available in all patients. Endpoints of this study were the composite outcome (defined as all-cause death or HF hospitalization) and all-cause death, analyzed by time from the date of 3-month CPX to first event. HF hospitalization required that a patient had typical symptoms and signs, treatment with diuretics, and at least an overnight hospital stay.

Data Analysis
In all patients who met the inclusion criteria, the relation-
Baseline Characteristics and Efficacy and Safety of the ET Program in All Patients

From January 2002 through October 2015, 340 patients met the inclusion criteria, and their baseline characteristics are shown in Table 1. The mean age of all patients was 62.1 years, and 78% were male. Most of the patients (95%) were treated with β-blockers. Among them, there were no exercise-related deaths or adverse events requiring hospitalization, including worsening HF, MI, or sustained ventricular tachycardia, during the 3-month ET program. The median

Statistical Analysis

Continuous variables, presented as mean±standard deviation, were compared by unpaired Student’s t-test and categorical variables by χ² test. Cumulative events were assessed by the Kaplan-Meier method, and differences in events were compared with a log-rank test. Cox proportional hazard analysis was used to assess the association between variables and outcomes. Variables with a value of P<0.1 in the univariate analysis were included in the multivariate analysis. A value of P<0.05 was considered to be statistically significant.

Results

Baseline Characteristics and Efficacy and Safety of the ET Program in All Patients

From January 2002 through October 2015, 340 patients met the inclusion criteria, and their baseline characteristics are shown in Table 1. The mean age of all patients was 62.1 years, and 78% were male. Most of the patients (95%) were treated with β-blockers. Among them, there were no exercise-related deaths or adverse events requiring hospitalization, including worsening HF, MI, or sustained ventricular tachycardia, during the 3-month ET program. The median
In the High-BNP patients, peak \( \dot{V}_O2 \) was significantly increased during the 3-month ET program (Table 2), and there was no significant difference in the change in peak \( \dot{V}_O2 \) during the ET program between the High-BNP and Low-BNP patients (+8.3\( \pm \)16.2\% vs. +10.1\( \pm \)15.9\%, respectively, P=0.31).

When the High-BNP patients were divided according to tertiles of the change in peak \( \dot{V}_O2 \) during the ET program (Poor-improvement group, n=57, Modest-improvement group, n=55, and Marked-improvement group, n=58), there were no significant differences among these groups in baseline characteristics, except for age, which was significantly lower in the Marked-improvement group, as compared with the other 2 groups (Table 3). The number of attendances at supervised ET sessions during the ET program was also similar among the 3 groups.

The change in peak \( \dot{V}_O2 \) during the 3-month ET program was \(-7.9\pm7.3\%\) in the Poor-improvement group, \(+6.6\pm3.1\%\) in the Modest-improvement group, and \(+25.8\pm12.0\%\) in the Marked-improvement group (P<0.0001). The change in peak \( \dot{V}_O2 \) in the Marked-improvement group (P<0.0001), and inversely correlated with the change in peak \( \dot{V}_O2 \) (R=−0.453, P<0.0001) (Figure 1A). Similarly, the percentage change in VE/\( \dot{V}_CO2 \) slope during the ET program was +7.3\%±12.7\%, −2.8\%±13.4\%, and −7.0\%±14.0\%, respectively (P<0.0001), and inversely correlated with the change in peak \( \dot{V}_O2 \) (R=−0.439, P<0.0001) (Figure 1B).

### Clinical Outcomes According to Change in Exercise Capacity in High-BNP Patients

In the High-BNP patients, clinical outcomes were compared according to tertiles of the change in peak \( \dot{V}_O2 \) during the ET program (Figure 2). The composite rate of all-cause death or HF hospitalization was significantly lower in the Marked-improvement group than in the Poor-improvement group (37.9\% vs. 54.4\%, respectively, P=0.036), but there was no significant difference between the Marked-improvement group and the Modest-improvement group (37.9\% vs. 47.3\%, respectively, P=0.19), or between the Modest-improvement group and the Poor-improvement group (P=0.57) (Figure 2A).

In the univariate Cox regression analysis, LVDd, LVDs, LAD, hemoglobin, BNP, peak \( \dot{V}_O2 \), and VE/\( \dot{V}_CO2 \) slope...
at baseline and the change in peak VO₂ during the ET program were all significantly related to the composite outcome, but age was not (Table 4). Multivariate analysis revealed that the change in peak VO₂ was a significant independent predictor of the combined endpoint after adjustment for baseline variables (Table 4). In addition, the prognostic impact of the change in peak VO₂ remained significant even after adjustment for the change in BNP (P=0.026) and after adjustment for the change in VE/VCO₂ slope (P=0.018). The change in BNP was also a significant independent predictor after adjustment for baseline variables (P=0.0001) and after adjustment for the change in peak VO₂ (P=0.0041). The change in VE/VCO₂ slope was a significant independent predictor after adjustment for baseline variables (P=0.0036), but not after adjustment for the change in peak VO₂ (P=0.28).

All-cause death tended to be lower in the Marked-improvement group than in the Poor-improvement group (8.6% vs. 24.6%, respectively, P=0.10) or between the Modest-improvement group (8.6% vs. 24.6%, respectively, P=0.056), but no significant difference was observed between the Marked-improvement group and the Modest-improvement group (8.6% vs. 20.0%, respectively, P=0.10) or between the Modest-improvement group and the Poor-improvement group (P=0.72) (Figure 2B). In the univariate Cox regression analysis, LVDd, LVDs, LAD, creatinine, hemoglobin, BNP, peak VO₂, and VE/VCO₂ slope at baseline and the change in peak VO₂ during the ET program were all significantly related to all-cause death, but age was not (Table 5). In the multivariate analysis, the change in peak VO₂ was a significant independent predictor of all-cause death after adjustment for baseline variables (Table 5).

**Discussion**

The present study demonstrated that in advanced HF patients with BNP ≥200 pg/mL and receiving current optimal medical therapy, the completion of a 3-month ET program significantly increased peak VO₂, and a greater increase in peak VO₂ was associated with greater decreases in BNP level and VE/VCO₂ slope and more favorable clinical outcomes. These findings suggested that even in such advanced HF patients, ‘good responders’ who achieve a greater improvement in exercise capacity by ET program have a greater improvement in hemodynamic status, ventilatory efficiency, and long-term outcomes than ‘poor responders’. Furthermore, we found that the change in peak VO₂ during the ET program was a powerful independent predictor of clinical outcome, but did not significantly correlate with baseline characteristics, except for age. This finding indicated the difficulty in predicting ‘good responders’ in an ET program from the subjects’ baseline characteristics and the prognostic importance of quantifying the response to ET program by serial CPX in the management of advanced HF patients.

Plasma BNP level is established as a reliable prognostic biomarker in HF patients. In consecutive HF patients who completed the 3-month ET program at our institution, half of them had a baseline BNP level ≥200 pg/mL, and we confirmed that these High-BNP patients had more advanced HF characteristics, including LV diameter, LV function, exercise capacity, and ventilatory efficiency, and a higher prevalence of noncardiac comorbidities such as chronic kidney disease and anemia than the Low-BNP patients. Nevertheless, the elevation of BNP level was not associated with an attenuated improvement in exercise capacity during the 3-month ET program.

Because peak VO₂ is an established powerful prognostic predictor in HF patients, the increase in peak VO₂ during an ET program would be expected to contribute a favorable outcome. Indeed, the prognostic significance of changes in exercise capacity by ET program has been confirmed in the modern era of medical HF treatment including β-blockers. Tabet et al demonstrated in HF patients with LVEF <45% (mean age 53 years, LVEF 30%, median BNP 331 pg/mL, mean follow-up 16 months) that an improvement in exercise capacity after an ET program was a strong prognostic factor of cardiac events. In a sub-study of the HF-ACTION (Heart Failure and a Controlled Trial Investigating Outcomes of Exercise Training) trial, Swank et al showed in HF patients with LVEF ≤35%...
(median age 59 years, LVEF 25%, BNP not reported, median follow-up 30 months) that every 6% increase in peak VO$_2$ was associated with an 8% lower risk of cardiovascular death or HF hospitalization. The present study extended the association between the efficacy of an ET program and clinical outcomes to older and more advanced HF patients receiving current optimal medical therapy (β-blockers, 94%) with LVEF <45% and BNP ≥200 pg/mL (median age 68 years, LVEF 24%, BNP 352 pg/mL) and longer follow-up period (median 46 months).

Passino et al have previously shown a significant inverse relationship between changes in peak VO$_2$ and changes in BNP level during ET program in HF patients (mean LVEF 34%, BNP 187 pg/mL). The present study confirmed this relationship in more advanced HF patients with higher baseline BNP level (mean LVEF 25%, BNP 436 pg/mL). Multiple potential mechanisms would be involved in the relationship. ET has been shown to improve LV diastolic function, autonomic nerve function, and endothelial function, all of which would contribute to alleviation of the hemodynamic burden imposed on the LV wall. Accordingly, patients who have a greater improvement in exercise capacity by ET would be likely to have a greater reduction in LV diastolic wall stress because of these beneficial effects, leading to a greater reduction in the BNP level.

An exaggerated ventilatory response to exercise, as expressed by elevated VE/VCO$_2$ slope, is responsible for breathlessness and associated with poor prognosis in HF patients. Although the mechanism of excess ventilatory effort during exercise in HF patients is not completely understood, one of the potential mechanisms is enhanced ergoreflex activity, which accompanies the skeletal muscle myopathy in HF. To the best of our knowledge, this is the first study to show a significant inverse relation between changes in peak VO$_2$ and changes in the VE/VCO$_2$ slope in HF patients during an ET program. This finding supports the notion that an improvement in a skeletal myopathy by ET would mitigate ergoreflex activation, leading to improved ventilatory efficiency. Another possible mechanism is that improvement in central hemodynamic function and ventilatory efficiency as a result of pharmacological treatment, not ET program, would be likely to have a positive effect on exercise capacity. However, the pharmacological treatment for HF, especially β-blockers, has been shown to have limited effect on exercise capacity.

Further studies are required to elucidate the precise mechanism of the relationship between changes in peak VO$_2$ and changes in BNP level or VE/VCO$_2$ slope.

The mean extent of the increase in peak VO$_2$ (8.3%) in our High-BNP patients was lower than that reported by a meta-analysis including 1,240 HF patients (13.0%). This may be explained by the relatively high age (median, 68 years) and the modest intensity ET program (40–60% of heart rate reserve) in our study. We observed no significant relationship between changes in peak VO$_2$ and the number of attendances at supervised ET sessions. This is likely because the effect of the ET program is influenced by the total amount of ET including home ET, not assessed in this study. Further studies are needed to determine the most appropriate ET protocol regarding intensity, duration, frequency, and modality for achieving the greatest improvement in exercise capacity.

The safety of ET programs has been assessed in many studies. Smart et al reported no deaths that were directly related to exercise during more than 60,000 patient-hours of ET. Among our 340 advanced HF patients who completed the 3-month ET program, no ET-related deaths or adverse events, including worsening HF, were observed. Among the 115 patients who did not complete the program during the study period, no deaths occurred but 6 patients were hospitalized for worsening HF without any apparent relationship to ET during the 3-month program. Furthermore, we did not find any deterioration in renal function during the ET program even in High-BNP patients, a finding that is similar to the result that we previously reported in patients after acute MI.

**Study Limitations**
First, it was a retrospective study involving a small number of patients without a control (non-exercise) group at a single institute. Although a prospective randomized study is essential to clarify the effect of ET programs on clinical outcomes in advanced HF patients, it would not be ethical to assign HF patients to a non-ET group at present when ET for HF patients is recommended in the guidelines. Second, we studied only the patients who had completed the 3-month ET program, which might have resulted in some bias towards a better outcome, because patients who dropped out of the ET program have been reported to have a worse outcome than those who completed such programs. Third, there might be some potentially important data for the assessment of outcome of HF patients, such as echocardiographic indices of LV diastolic function at baseline or change in LV function during the ET program, which were not available in the present study. Finally, we studied HF patients with reduced LVEF (<45%), and therefore our findings cannot be generalized to HF patients with preserved LVEF.

**Conclusions**
In advanced HF patients with a high BNP level who completed a 3-month ET program, exercise capacity was significantly improved, similarly to those with a low BNP level, and a greater improvement in exercise capacity by the ET program was associated with greater decreases in BNP level and VE/VCO$_2$ slope and more favorable long-term clinical outcomes. These findings indicated that even advanced HF patients are likely to benefit from ET and should be referred to ET programs, and, conversely, that those with a poor improvement in exercise capacity during an ET program should be watched carefully for worsening outcomes.
