Background: Lipoprotein lipase (LPL) plays an important role in triglyceride metabolism. It is translocated across endothelial cells to reach the luminal surface of capillaries by glycosylphosphatidylinositol-anchored high-density lipoprotein binding protein 1 (GPIHBP1), where it hydrolyzes triglycerides in lipoproteins. MicroRNA 377 (miR-377) is highly associated with lipid levels. However, how miR-377 regulates triglyceride metabolism and whether it is involved in the development of atherosclerosis remain largely unexplored.

Methods and Results: The clinical examination displayed that miR-377 expression was markedly lower in plasma from patients with hypertriglyceridemia compared with non-hypertriglyceridemic subjects. Bioinformatics analyses and a luciferase reporter assay showed that DNA methyltransferase 1 (DNMT1) was a target gene of miR-377. Moreover, miR-377 increased LPL binding to GPIHBP1 by directly targeting DNMT1 in human umbilical vein endothelial cells (HUVECs) and apolipoprotein E (ApoE)-knockout (KO) mice aorta endothelial cells (MAECs). In vivo, hematoxylin-eosin (H&E), Oil Red O and Masson’s trichrome staining showed that ApoE-KO mice treated with miR-377 developed less atherosclerotic plaques, accompanied by reduced plasma triglyceride levels.

Conclusions: It is concluded that miR-377 upregulates GPIHBP1 expression, increases the LPL binding to GPIHBP1, and reduces plasma triglyceride levels, likely through targeting DNMT1, inhibiting atherosclerosis in ApoE-KO mice.

Key Words: Atherosclerosis; DNA methyltransferase 1 (DNMT1); Glycosylphosphatidylinositol-anchored high-density lipoprotein-binding protein 1 (GPIHBP1); Lipoprotein lipase (LPL); MicroRNA-377

Atherosclerosis is the common pathological basis of cardiovascular and cerebrovascular diseases. Lipid metabolism disorder, such as the aberrant elevation of triglyceride levels, is an independent risk factor for atherosclerosis. Increasing evidence suggests that microRNAs (miRNAs) play a critical role in lipid metabolism and atherosclerosis. Previously, our colleagues showed that miR-186, miR-134, and miR-467b induce lipid accumulation and activate an inflammatory response in macrophages through regulating lipoprotein lipase (LPL). MicroRNA-377 (miR-377), a polyphonic miRNA, is known to be involved in oxidative stress, inflammation, angiogenesis in ischemic hearts, and the cardiac regenerative ability. In addition, miR-377 levels are closely associated with lipid levels in vivo, indicating its role in regulating lipid metabolism. However, the molecular mechanisms for miR-377-modulated triglyceride metabolism in the development of atherosclerosis are poorly studied.

DNA methylation, one of the earliest ways of epigenetic modifications, exists in all higher organisms. The cytosine rings of CpG sequence are subjected to methylation modifications in response to DNA methyltransferases (DNMTs), leading to silencing of gene expression. DNMT1, one of the most important DNA methyltransferases, is responsible for maintaining the methylated state of DNA after replication, which allows the methylation...
pattern to be passed on to the progeny cells. Overexpression of DNMT1 in macrophages induces pro-inflammatory cytokines production and atherosclerosis development. Moreover, DNMT1 is associated with elevated triglyceride levels. However, the substrate of DNMT1 involved in triglyceride metabolism has not yet been fully elucidated.

LPL plays an important role in triglyceride metabolism. After secretion by parenchymal cells (e.g., cardiomyocytes and adipocytes), LPL is translocated across endothelial cells to reach the luminal surface of capillaries by glycosylphosphatidylinositol-anchored high-density lipoprotein (HDL) binding protein 1 (GPIHBP1), where it hydrolyzes triglycerides (TG) in lipoproteins. Some studies have shown that GPIHBP1 stabilizes LPL and prevents its inhibition of angiopeptin-like 3 (ANGPTL3) and angiopeptin-like 4 (ANGPTL4), but GPIHBP1 has no effect on the LPL activity. Recently, many noteworthy clinical studies reported that patients with mutations in GPIHBP1 are suffered from severe hypertriglyceridemia. Furthermore, it has been reported that GPIHBP1 autoantibodies block the ability of GPIHBP1 to bind and transport LPL, which interferes with the LPL-mediated processing of triglyceride-rich lipoproteins and consequently causes severe hypertriglyceridemia. Global deletion of GPIHBP1 in mice leads to elevated plasma levels of triglyceride. Therefore, GPIHBP1 is an important regulator in reducing plasma triglyceride levels. However, the regulatory mechanism of GPIHBP1 expression, especially epigenetic regulation of GPIHBP1, is still largely unknown.

Here, we reported that patients with hypertriglyceridemia showed reduced plasma levels of miR-377 mRNA. Overexpression of miR-377 reduces triglyceride levels and atherosclerotic plaques in apolipoprotein E (ApoE)-knockout (KO) mice. Mechanistically, miR-377 downregulated DNMT1, which increased the binding of LPL to GPIHBP1 and consequently reduces plasma triglyceride levels. Taken together, the results suggest that miR-377 may act as a novel pharmacologic target for atherosclerosis therapy.

**Methods**

**Cell Culture**

Human umbilical vein endothelial cells (HUVECs) and HEK 293T cells were obtained from Cell Bank of the Chinese Academy of Sciences (Shanghai, China). HUVECs were maintained at 37°C using an endothelial cell growth medium 2 (EGM-2) bullet kit supplemented with 2% fetal bovine serum (FBS), endothelial cell growth supplement, 50 µg/mL heparin, 100 IU/mL penicillin, 100 µg/mL streptomycin, 2.5 µg/mL amphotericin B, and other supplements (Lonza, Switzerland). The endothelial cell growth supplement contains vascular endothelial growth factor (VEGF), human fibroblast growth factor-B (FGF-B), insulin-like growth factor 1 (IGF-1), and epidermal growth factor (EGF) (Lonza, Switzerland). The other supplements include hydrocortisone, ascorbic acid, gentamicin and insulin (Lonza, Switzerland). HEK 293T cells were maintained as adherent monolayers by serial passage in Dulbecco’s modified Eagle’s medium (DMEM) (HyClone, USA) containing 10% FBS. All HUVECs and HEK 293T cells were maintained in an incubator with a saturated humidity environment of 95% air–5% CO2 at 37°C.

**Western Blot Analysis**

Cells were lysed in RIPA buffer (Sigma, St Louis, MO, USA) on ice for protein extraction, as described previously. The protein content was assayed by BCA protein assay reagent (Pierce, USA). A sample of 50 µg protein was loaded to SDS-PAGE, and then transferred to the polyvinylidene difluoride (PVDF) (Millipore Corporation, USA) membranes. The membrane was blocked with 5% non-fat dry milk (NFDM) in TBST (Tris 0.05% Tween-20) at 4°C for 4 h. Both GPIHBP1 and LPL antibodies were purchased from Abcam (Cambridge, UK), and β-actin antibody (AF0003) from Beyotime. The membrane was incubated with a 1:1,000 dilution of primary antibody overnight at 4°C, washed with TBST and incubated with a 1:2,500 dilution of horseradish peroxidase (HRP)-conjugated secondary antibody diluted in TBST containing 5% NFDM at room temperature for 2 h. Immunoreactive bands were visualized with Tanon-5500 Chemiluminescent Imaging System (Tanon, China) and BeyoECL Plus (Beyotime, China).

**Real-Time Quantitative PCR (qPCR) Analysis**

qPCR analysis was performed as described previously. Cells total RNA was extracted using TRIzol reagent (Invitrogen, Carlsbad, CA, USA) according to the manufacturer’s introduction. Reverse transcription was conducted by a High-Capacity cDNA reverse transcription kit (Takara), qPCR was performed by SYBR Green detection chemistry with a Light Cycler Run 5.32 Real-Time PCR System (Roche, Swiss). The analyses of all qPCR Melt curve analyses were performed and showed to produce a single DNA duplex. Quantitative measurements were confirmed by the ΔΔCT method. In these experiments, gene expression data were normalized to GAPDH levels. The primers and their sequences are shown in **Table S1**.

**Bisulfite Sequencing of the GPIHBP1 Promoter**

DNA was extracted from cells using the Dneasy Kit (Qiibo, USA), according to the manufacturer’s instruction. Bisulfite modification was executed by using an EZ DNA Methylation-Direct™ Kit (Zymo Research, USA). After bisulfite conversion, the GPIHBP1 promoter was amplified with the following primers: forward, 5’-CGGTTGCAAC GGGGACATGTGC-3’, and reverse, 5’-GACCAGTTG CCCCCATTACG-3’. PCR was performed with an EpiTaq HS enzyme (Takara, JP). After purified using a QIAquick Gel Extraction Kit (Qiagen Inc., CA), the PCR fragment was cloned into the TA vector (Invitrogen, USA). The sequences were determined with an ABI PRISM® 3700 Genetic Analyzer (Applied Biosystems, USA), and data were summarized by using the web-based software, QUMA (http://quma.cdb.riken.jp/). After, the chi-squared test was used to analyze the rate of each methylation variation.

**Binding of LPL to GPIHBP1 Assay**

After treated with PIPCL, cells were treated with miR-377 mimic or miR-377 inhibitor. Twenty-four hours later, the GPIHBP1-expressing HUVECs continue to grow on fibronectin-coated plates or coverslips were incubated with Flag-tagged human LPL for 2 h at 4°C. After washing extensively in 1×PBS, cells were treated with heparin (250 U/mL) to release surface-bound LPL. The cell lysates were collected and the heparin-released LPL was examined for the binding of LPL to GPIHBP1 by Western blot.
MicroRNA-377 Inhibits Atherosclerosis

Results

MicroRNA-377 Binds to DNM1t’s 3’-Untranslated Region (3’-UTR) and Inhibits DNM1t Expression and Activity

Analysis using microRNA.org-Targets and Expression revealed a predicted binding site of miR-377 on the 3’-UTR of DNM1t, which is highly conserved among different species (Figure S1A). Several target gene prediction algorithms also suggest a highly homologous sequence of
and expression of DNMT1 in cells. As shown in Figure 2A, overexpression of miR-377 mimic markedly increased its mRNA levels and significantly reduced the activity of DNMT1. An opposite phenotype was observed when the cells were treated with miR-377 inhibitor; miR-377 levels were reduced but DNMT1 activity was increased (Figure 2B). Furthermore, miR-377 mimic reduced, while miR-377 inhibitor increased, the mRNA and protein levels of DNMT1 mRNA and protein in endothelial cells in a concentration-dependent manner (Figure 2C–E). Consistently, the effects of miR-377 mimic and inhibitor on DNMT1 expression were time-dependent (Figure 2F–H). Collectively, these findings indicate that miR-377 repressed DNMT1 activity and expression potentially by targeting 3’-UTR of DNMT1 in HUVECs.

DNMT1 Catalyzes GPIHBP1 Promoter Methylation and Attenuates Its Expression

CpG islands are mainly located in the promoter and the 5’-UTR of genes, although they can also be found in other regions of the genome. Methylation of CpG islands in the promoter region can affect gene expression by recruiting repressive chromatin modifications such as histone modifications and DNA methylation. In the present study, we found that DNMT1 catalyzes the methylation of the GPIHBP1 promoter, which attenuates its expression. This finding is consistent with previous studies that have shown a role for DNMT1 in the regulation of gene expression through promoter methylation.

The miR-377 binding site in the 3’-UTR of human DNMT1 mRNA (Targetscan, miRDB, and microRNA.org) that is also highly conserved among different species (Figure S1B). Further, the free energy scores (miRnaViewer and RNAhybrid) for the hybridization between miR-377 and DNMT1 are low in humans (Figure S1C). Together, these predictions suggest that miR-377 may be a potentially important regulator of DNMT1. To investigate this possibility, we constructed a luciferase reporter vector containing wild-type DNMT1 3’-UTR with the miR-377 homologous sequence or a mutant DNMT1 3’-UTR, in which the miR-377 homologous sequence was eliminated (Figure S1D). When compared with the control in HEK 293T cells, miR-377 mimic had no effect on the luciferase activity of GPIHBP1 and LPL (Figure S1F,G) but significantly decreased the relative luciferase activity of the wildtype DNMT1 3’-UTR reporter, while had no effect on the mutant DNMT1 3’-UTR (Figure S1E).

Next, we examined the effects of miR-377 on the activity and expression of DNMT1 in cells. As shown in Figure 2A, overexpression of miR-377 mimic markedly increased its mRNA levels and significantly reduced the activity of DNMT1. An opposite phenotype was observed when the cells were treated with miR-377 inhibitor; miR-377 levels were reduced but DNMT1 activity was increased (Figure 2B). Furthermore, miR-377 mimic reduced, while miR-377 inhibitor increased, the mRNA and protein levels of DNMT1 mRNA and protein in endothelial cells in a concentration-dependent manner (Figure 2C–E). Consistently, the effects of miR-377 mimic and inhibitor on DNMT1 expression were time-dependent (Figure 2F–H). Collectively, these findings indicate that miR-377 repressed DNMT1 activity and expression potentially by targeting 3’-UTR of DNMT1 in HUVECs.

DNMT1 Catalyzes GPIHBP1 Promoter Methylation and Attenuates Its Expression

MicroRNA-377 Inhibits Atherosclerosis

The GPIHBP1 CGI 1 and CGI 2 are extended across 328bp and 318bp containing a CG content of 62.8% and 59.7%, with an observed-to-expected CpG ratio of 0.99 and 0.78 respectively (Table S3). Detailed sequence analysis indicates the presence of a central region that covers the midsection first exon region of genes. We employed the UCSC Human Genome Browser and NCBI gene bank (http://www.ncbi.nlm.nih.gov/pubmed/) to define the genomic features of GPIHBP1 promoter sequence. We found that the GPIHBP1 promoter contains 2 well-defined genic CGIs clustered with a high density of CpG locus, as analyzed with online tools (https://www.ebi.ac.uk/services) (Figure S2A,B). The GPIHBP1 CGI1 and CGI2 are extended across 328bp and 318bp containing a CG content of 62.8% and 59.7%, with an observed-to-expected CpG ratio of 0.99 and 0.78 respectively (Table S3). Detailed sequence analysis indicates the presence of a central region that covers the midsection.
DNA methylation levels within the GPIHBP1 promoter at sites 1, 2, 3, 5, 6, 7 and 10 of CGI 1, and at sites 2, 3, 5, 6, 7, 8, 9, 11, 12, 13 and 15 of CGI 2 (Figure 3B). The increase of DNA methylation levels in these sites, except for site 10 in CGI 1, could be blocked by inhibition of DNMT1, indicating the important role of DNMT1 in DNA methylation of GPIHBP1 (Figure 3B, C). Although there was no difference at some sites, the methylation level of the GPIHBP1 promoter was totally increased in response to DNMT1 treatment (Figure 3A).

Figure 4. MicroRNA-377 (miR-377) mediates the binding of lipoprotein lipase (LPL) to glycosylphosphatidylinositol-anchored high-density lipoprotein binding protein 1 (GPIHBP1) by inhibiting DNA methyltransferase 1 (DNMT1). (A, B) GPIHBP1 promoter methylation levels were analyzed when cells were transfected with miR-377 mimic, DNMT1, miR-377 mimic+DNMT1 and miR-377 inhibitor, shDNMT1, and miR-377 inhibitor+shDNMT1 through bisulfite sequencing. (C, D) GPIHBP1 mRNA and protein expression were detected by quantitative polymerase chain reaction (qPCR) or western blotting, and treated with miR-377 mimic together with mimic-neg or DNMT1 as indicated respectively. (E, F) GPIHBP1 mRNA and protein expression were, respectively, examined by qPCR or western blotting and treated with miR-377 inhibitor together with inhibitor-neg or DNMT1 as indicated. (G, H) miR-377 increases the binding of LPL to GPIHBP1 by inhibiting DNMT1. The heparin-released LPL was examined for the binding of LPL to GPIHBP1 by western blotting (top row). Data are presented as the mean±SEM, n=3. *P<0.05 vs. Control and #P<0.05 vs. DNMT1 or shDNMT1 respectively.

with a high CpG load, indicating that GPIHBP1 promoter might be a target of DNA methylation.

To assess the role of DNMT1 in regulating the methylation of GPIHBP1 in HUVECs, we detected the methylation levels of different CG locus in the GPIHBP1 promoter by using bisulfite sequencing. We found that the methylation levels of the GPIHBP1 promoter were significantly increased with DNMT1 treatment, which was blocked by inhibition of DNMT1 with 5-Aza-dC (Figure 3A). Detailed analyses revealed that DNMT1 significantly increased DNA methylation levels within the GPIHBP1 promoter at sites 1, 2, 3, 5, 6, 7 and 10 of CGI 1, and at sites 2, 3, 5, 6, 7, 8, 9, 11, 12, 13 and 15 of CGI 2 (Figure 3B, C). The increase of DNA methylation levels in these sites, except for site 10 in CGI 1, could be blocked by inhibition of DNMT1, indicating the important role of DNMT1 in DNA methylation of GPIHBP1 (Figure 3B, C). Although there was no difference at some sites, the methylation level of the GPIHBP1 promoter was totally increased in response to DNMT1 treatment (Figure 3A).
**MicroRNA-377 Inhibits Atherosclerosis**

Next, we detected the effect of DNMT1 on GPIHBP1 expression. As shown in Figure 3D,E, DNMT1 overexpression increased both activity and protein level of DNMT1. In contrast, DNMT1 inhibition by either 5-Aza-dC or short hairpin DNMT1 (shDNMT1) negatively regulated DNMT1 activity and expression (Figure 3D,E). Most importantly, DNMT1 overexpression inhibited, while DNMT1 inhibition increased GPIHBP1 mRNA and protein levels (Figure 3F,G). Together, these findings indicate that DNMT1 enhances DNA methylation in the promoter region of GPIHBP1, inhibiting GPIHBP1 expression.

miR-377 Decreases GPIHBP1 Promoter Methylation and Increases the Binding of LPL in GPIHBP1-Expressing Cells

Considering the inhibitory effect of miR-377 on DNMT1 activity, we examined the effect of miR-377 on GPIHBP1 expression. Treatment with miR-377 mimic significantly decreased DNA methylation of GPIHBP1 and blocked DNMT1-induced increase in DNA methylation of GPIHBP1 (Figure 4A). Conversely, treatment of miR-377 inhibitor increased DNA methylation of GPIHBP1 and restored the inhibitory effects induced by DNMT1 knockdown (Figure 4B). Consistently, miR-377 mimic increased DNA methylation of GPIHBP1 and restored the inhibitory effects induced by DNMT1 knockdown.

Figure 5. MicroRNA-377 (miR-377) ameliorates the development of atherosclerosis. Atherosclerotic lesions were examined in 12-week-old apolipoprotein E (ApoE)-knockout (KO) mice that were treated with miR-377 agomir negative control (AG-NC), miR-377 agomir (AG), miR-377 antagomir negative control (AN-NC), or miR-377 antagomir (AN) through tail vein injections. ApoE-KO mice were fed with high fat/high cholesterol diet. (A) Representative images of plaques (blue arrows) in aortic arches and thoracic aortas of ApoE-KO mice. (B) Representative images and quantification of atherosclerotic lesion areas in the en face analysis of the entire aorta with Oil Red O staining. (C) Representative micrographs of hematoxylin-eosin staining in the aortic sinus. (D) Characterization of aortic sinus in atherosclerotic lesion areas by Oil Red O staining. (E) Representative microscopic images and quantification of atherosclerotic plaque collagen content in the aortic sinus by Masson’s trichrome staining. Representative images of sections from each group are accompanied by graphs summarizing the data. (Original magnification×104 [C–E]). Data are presented as the mean±SEM, n=10. **P<0.01 vs. AG-NC and ##P<0.01 vs. AN-NC.
miR-377 Inhibits the Development of Atherosclerosis in ApoE-KO Mice

We further examined the effects of miR-377 on the development of atherosclerosis in ApoE-KO mice. Mice treated with AG displayed a significant reduction in atherosclerotic plaque area, while AN treatment increased plaque areas when compared with their negative controls (Figure 5A). We also observed that the severity of lipid deposition in the atherosclerotic plaque of aortas of mice was significantly decreased in AG-treated mice, but increased in AN-treated mice (Figure 5B). We further investigated the effects of miR-377 on plaque formation, lipid deposition, and collagen content in aortic sinus. Similarly, the aortic sinus plaque area and lipid deposition were much less than in AG-treated mice, but much greater in AG-NC-treated mice when compared to their control groups (Figure 5C–F). These findings indicate that DNMT1 may mediate the effects of miR-377 on Gpihbp1 expression.

Next, we determined whether miR-377 affected the binding of LPL to Gpihbp1 on the surface of endothelial cells. Endothelial cells were treated with various conditions, as indicated in Figure 4G, H, and then incubated with LPL. Protein expression in cell lysate and heparin-released LPL was detected by Western Blot. miR-377 mimic significantly increased Gpihbp1 expression and the binding of LPL to Gpihbp1 on the cell surface (Figure 4G). Conversely, miR-377 inhibitor decreased Gpihbp1 expression and the levels of bound LPL (Figure 4H). Further, overexpression of DNMT1 reduced, while knockdown of DNMT1 increased, Gpihbp1 expression and the binding of LPL to Gpihbp1 (Figure 4G, H). Importantly, DNMT1 suppressed the miR-377-induced increase in Gpihbp1 expression and the binding of LPL to Gpihbp1 (Figure 4C–G), and knockdown of DNMT1 almost completely suppressed the effect of miR-377 inhibition (Figure 4E–H). These findings suggest the possibility that miR-377 silences DNMT1, leading to increased Gpihbp1 expression and the binding of LPL to Gpihbp1 on the surface of endothelial cell.

miR-377 Inhibits the Development of Atherosclerosis in ApoE-KO Mice

We further examined the effects of miR-377 on the development of atherosclerosis in ApoE-KO mice. Mice treated with AG displayed a significant reduction in atherosclerotic plaque area, while AN treatment increased plaque areas when compared with their negative controls (Figure 5A). We also observed that the severity of lipid deposition in the atherosclerotic plaque of aortas of mice was significantly decreased in AG-treated mice, but increased in AN-treated mice (Figure 5B). We further investigated the effects of miR-377 on plaque formation, lipid deposition, and collagen content in aortic sinus. Similarly, the aortic sinus plaque area and lipid deposition were much less than in AG-treated mice, but much greater in AG-NC-treated mice when compared to their control groups (Figure 5C–D). Masson’s trichrome staining results showed that the collagen content in aortic sinus was increased in AG-treated mice but reduced in AN-treated mice, suggesting that miR-377 increases the stability of atherosclerotic plaque at the aortic sinus (Figure 5E). Together, the results indicated the anti-atherogenic role of miR-377 in ApoE-KO mice.
MicroRNA-377 Inhibits Atherosclerosis

MicroRNA-377 Reduces Triglyceride Levels Through the DNMT1-GPIHB1-LPL Axis in ApoE-KO Mice

To investigate the potential contribution of the DNMT1-GPIHB1-LPL pathway to the effect of miR-377 on the development of atherosclerosis in ApoE-KO mice, we determined the expression of DNMT1 and GPIHB1 in the aortic arch of mice in each group. AG treatment markedly decreased, while AN treatment increased the levels of DNMT1 mRNA, protein expression and activity in mice (Figure 6A–C). As expected, the levels of GPIHB1 mRNA and protein expression, and the binding of LPL to GPIHB1 on the surface of aorta endothelial cells (MAECs) were increased in AG-treated mice, but decreased in AN-treated mice (Figure 6D–F). AG treatment also significantly reduced plasma levels of TG, TC, and LDL-C, but had no effect on plasma HDL-C in ApoE-KO mice fed the Western-type diet. AN treatment also did not change plasma levels of HDL-C, but significantly increased plasma levels of TG, TC, and LDL-C (Table). These data indicate that miR-377 might regulate plasma triglyceride levels via the miR-377-DNMT1-GPIHB1-LPL axis in ApoE-KO mice.

Discussion

In this study, we have demonstrated the roles of miR-377 and DNMT1 in triglyceride metabolism and in the development of atherosclerosis. Our findings revealed that miR-377 reduced DNA methylation in GPIHB1 promoter through directly targeting DNMT1, thereby increasing GPIHB1 expression and the binding of LPL to GPIHB1.
DNMT1. cancerous phenotypes of pancreatic cells through inhibiting lated senescence in human skin fibroblasts and reversed promoter may associate with hypertriglyceridemia. region, suggesting that aberrant methylation of GPIHBP1 lumen and creates “a platform for lipolysis”. We showed cally, GPIHBP1 offers a binding site for LPL in the capillary expression was significantly reduced in patients with high expression was significantly reduced in patients with high triglyceride metabolism and affect the development of atherosclerosis. 8. Joladarashi D, Garikipati VN, Thandavarayan RA, Verma SK, et al. miR-377-mediated triglyceride metabolism by inhibiting DNMT1. This suggests that miR-377 mediates triglyceride metabolism by inhibiting DNMT1. Moreover, miR-377 reduces plasma triglyceride levels and suppresses the development of atherosclerosis. Collectively, our results strongly demonstrate that miR-377 directly inhibits DNMT1 and subsequently downregulates DNA methylation levels of the GPIHBP1 promoter, increasing GPIHBP1 expression and the binding of LPL to GPIHBP1. This reduces plasma triglyceride levels and suppresses the development of atherosclerosis (Figure 7). These data have shed new light on the mechanism underlying epigenetic regulation of GPIHBP1, and may provide a new target in regulating triglyceride metabolism and preventing atherosclerosis.
