Background: It has previously been demonstrated that apolipoprotein A-1 (apoA-1) binding protein (AIBP) promotes apoA-1 binding to ATP-binding cassette transporter A1 (ABCA1) and prevents ABCA1 protein degradation so as to inhibit foam cell formation. Because apoA-1 inhibits inflammatory signaling pathways, whether AIBP has an inhibitory effect on inflammatory signaling pathways in THP-1-derived macrophages is investigated.

Methods and Results: Analysis of inflammation-related gene expression indicated that AIBP decreased lipopolysaccharide (LPS)-mediated macrophage inflammation. AIBP significantly prevented NF-κB nuclear translocation. Further, AIBP prevented the activation of mitogen-activated protein kinases (MAPKs), including p38 MAPK, extracellular-signal regulated kinase and c-Jun N-terminal kinase. AIBP decreased MyD88 expression at both mRNA and protein levels, but did not have any effect on TLR4 expression. Moreover, treatment with both AIBP and apoA-1 decreased the abundance of TLR4 in the lipid raft fraction. AIBP lacking 115-123 amino acids (Δ115-123), however, did not have such effects as described for intact AIBP. In addition, knockdown of ABCA1 inhibited the effects of AIBP on inflammatory factor secretion.

Conclusions: These results suggest that AIBP inhibits inflammatory signaling pathways through binding to apoA-1 and stabilizing ABCA1, and subsequent alteration of lipid rafts and TLR4 in the cell membrane.

Key Words: Apolipoprotein A-1 (apoA-1); Apolipoprotein A-1 binding protein (AIBP); ATP-binding cassette transporter A1 (ABCA1); Atherosclerosis; Inflammation

Inflammation plays important roles in the development of atherosclerosis, the main cause of coronary artery disease (CAD). Accumulation of macrophages into the intima correlates with progression of atherosclerotic plaque and plaque rupture. On one hand, macrophages uptake lipids and cholesterol derivatives, resulting in foam cell formation that contributes to fatty streaks. On the other hand, macrophages are the major contributors to the inflammatory response through their secretion of pro-inflammatory mediators (chemokines, cytokines, reactive oxygen and nitrogen species) and matrix-degrading proteases and through their eventual cell death, such as necrosis and apoptosis.

Previous studies have suggested that the reverse cholesterol transport (RCT) mediated by high-density lipoprotein (HDL) particles has a relevant anti-atherogenic potential. In this process, the ATP-binding cassette transporter A1 (ABCA1) releases intracellular cholesterol to apolipoprotein A-1 (apoA-1) to form HDL, which is defined as the first step of RCT. Our laboratory has also demonstrated that maintaining the abundance of ABCA1 protein can effectively ensure RCT and prevent the development of atherosclerosis. In addition to its role in cholesterol efflux, ABCA1 has recently been considered as an anti-inflammation...
AIBP Inhibits Inflammatory Signaling Pathways

Cell Culture
Human THP-1 and HEK 293T cells were obtained from the Cell Bank of the Chinese Academy of Sciences (Shanghai, China). THP-1 was cultured in RPMI 1640 (Solarbio, China) supplemented with 10% fetal bovine serum (FBS) at 37°C and 5% CO₂. After 3–4 days, THP-1 cells were treated with phorbol-12-myristate-13-acetate (PMA, 160 nmol/L; Sigma, USA) for 24 h to differentiate THP-1 to macrophages before they were used in experiments. HEK 293T cells were cultured in Dulbecco’s Modified Eagle Medium (DMEM) containing 10% FBS.

Generation of Recombinant Adeno-Associated Virus
The gene fragments encoding human AIBP and AIBP(Δ115-123) were generated by reverse transcription polymerase chain reaction (RT-PCR) and overlap extension polymerase chain reaction (OE-PCR) from the mRNA of human liver cDNA library. Both AIBP and AIBP(Δ115-123) cDNA were cloned into recombinant adeno-associated virus 9 (rAAV9) with a FLAG tag (Cell Biolabs, San Diego, USA) to construct rAAV-AIBP and rAAV-AIBP(Δ115-123) for amplification. Positive recombinants were loaded into HEK 293T cells using a rAAV helper-free system (Stratagene, USA) for virus packaging and propagation.

Enzyme-Linked Immunosorbent Assay (ELISA)
The levels of inflammatory factors were quantitated using an ELISA kit (Boster, China). Briefly, 1×10⁶ THP-1 macrophage-derived THP-1 macrophages were incubated with or without 25 mg/mL apoA-1 and 100 ng/mL LPS before testing. Secretion levels of TNF-α (A), IL-6 (B), MCP-1 (D) and IL-1β (C) were detected by using an ELISA. Values represent means from 3 individual experiments. *P<0.05 vs. the LPS group. #P<0.05 vs. the apoA-1 group. AIBP, apolipoprotein A-1 binding protein; LPS, lipopolysaccharides; THP-1, a human monocytic cell line derived from an acute monocytic leukemia patient; apoA-1, apolipoprotein A-1; TNF-α, tumor necrosis factor-α; IL, interleukin; MCP-1, monocyte chemoattractant protein 1; ELISA, enzyme-linked immunosorbent assay.
Figure 2. Effects of AIBP on the activation of NF-κB. THP-1 macrophages were incubated with 25 mg/mL apoA-1 and 100 ng/mL LPS (A, B) or IL-1β before testing (C, D). The nuclear and cytoplasmic levels of NF-κB p65 were measured by using Western blotting analysis. *P<0.05 vs. control group. Abbreviations as in Figure 1.

Figure 3. Effects of AIBP on the activation of MAPKs. THP-1 macrophages were incubated with 25 μg/mL apoA-1 and 100 ng/mL LPS before testing. The levels of p38, p-p38 (A, B), ERK1/2, p-ERK1/2 (C, D), JNK1/2 and p-JNK1/2 (E, F) were measured by Western blot analysis. *P<0.05 vs. control group. MAPKs, mitogen-activated protein kinases; ERK, extracellular signal-regulated kinases; JNK, c-Jun N-terminal kinases. Other abbreviations as in Figure 1.
phages were incubated with 100 ng/mL lipopolysaccharide (LPS) or 10 ng/mL interleukin-1β (IL-1β), 25 μg/mL apoA-I, and 0.2 μg/mL AIBP or AIBP(Δ115-123), followed by the collection of the supernatants. The concentrations of tumor necrosis factor-α (TNF-α), interleukin-6 (IL-6), monocyte chemoattractant protein-1 (MCP-1), and IL-1β in supernatants were measured by sandwich ELISA following the manufacturer’s instructions. The cytokine standards were used to generate standard curves. Quantitative determinations in three different experiments were performed.

Western Blotting Assay

Protein extracts from tissues or cells were quantified and subjected to sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE), transferred to polyvinylidene difluoride (PVDF) membranes (Millipore Corporation, USA), and incubated with primary and secondary antibodies, respectively. Primary antibodies were: p65 (Beyotime, 1:500); p38 MAPK (Beyotime, 1:1,000); p-p38 MAPK (Beyotime, 1:1,000); ERK1/2 (Beyotime, 1:1,000); p-ERK1/2 (Beyotime, 1:1,000); JNK1/2 (Beyotime, 1:1,000); p-JNK1/2 (Beyotime, 1:1,000); TLR4 (ABCAM, 1:500); β-actin (Proteinteck, 1:2,000). Secondary antibodies were: HRP-labelled Goat Anti-Mouse IgG(H+L) (Beyotime, 1:1,000) and horseradish peroxidase (HRP)-labelled Goat Anti-Rabbit IgG(H+L) (Beyotime, 1:1,000). Immunoreactive bands were visualized with Tanon 5500 (China) and BeyoECL Plus (Beyotime, China).

RNA Extraction and Real-Time PCR

Total RNA in THP-1 macrophages was extracted with the TRIzol reagent and converted to cDNA using PrimeScript RT reagent kits, followed by real-time PCR of MyD88, TLR4 and the housekeeping gene, GAPDH, by TaqMan Gene Expression Assays. The ΔΔCt method was used to ascertain differences between genotypes in MyD88 and TLR4 expression level standardized against the reference gene, GAPDH. The sequences of the real-time PCR primers were as follows: human MyD88, 5’-AGGAGGAAATCTGTGCTCTACT-3’ and 5’-CATTTCATGTGCACTGAG

![Figure 4](image-url)
Alexa Fluor 594-labeled cholera toxin B (CTB, Invitrogen) for 15 min at 4°C was added to the cells. The cells were washed with PBS and incubated with the anti-CTB antibody (ABCAM, USA, 1:100) for 15 min at 4°C to cross-link CTB and the lipid raft. After washing with PBS, cells were fixed with 4% formaldehyde for 15 min. Nuclear DNA was labeled with a 4',6-diamidino-2-phenylindole (DAPI) staining solution (Beyotime, China) and photographed with an Olympus IX73 fluorescent microscope.

Transfection of siRNA
Pre-designed siRNA-targeting ABCA1 and the corresponding control siRNAs were purchased from Biology Engineering Corporation (Shanghai, China). THP-1 macrophages (2×10^6 cells/well) were transfected with the siRNA of ABCA1 or control siRNA using Lipofectamine 2000 (Invitrogen) according to the manufacturer’s protocol. After 48 h incubation, ABCA1 protein level was detected using Western blot analysis.

Statistical Analysis
All data are presented as means±SD and evaluated using Student’s t-test of 2 groups (2 tailed) or one-way ANOVA with Tukey’s post-hoc test or Dunnnett’s post-hoc test. A value of P<0.05 was considered statistically significant. All the statistical analyses were performed using Prism software (GraphPad Software, La Jolla, CA).
**Results**

AIBP Inhibits the Secretion of Proinflammatory Cytokines Induced by LPS

Macrophage inflammatory response is a key component in the development of atherosclerosis. To investigate whether AIBP has an effect on macrophage inflammation, we detected the secretion of inflammatory factors in THP-1 macrophages induced by LPS after AIBP treatment. Our results revealed that apoA-1 prevented LPS-stimulated expression and secretion of proinflammatory factors, such as tumor necrosis factor-α (TNF-α), interleukin 6 (IL-6), monocyte chemotactic protein 1 (MCP1) and interleukin-1β (IL-1β). Co-treatment with AIBP and apoA-1 further inhibited the secretion of inflammatory factors, suggesting AIBP has significant anti-inflammatory functions (Figure 1). However, AIBP lacking amino acids from 115 to 123 (Δ115-123) did not have any effect on inflammatory factor secretion (Figure 1). We previously showed that this domain was responsible for AIBP binding to apoA-1. Importantly, similar results were also obtained with HepG2 cells (Figure S1). Taken together, our results demonstrated that AIBP inhibits the secretion of proinflammatory cytokines induced by LPS through binding to apoA-1.

AIBP Inhibits Nuclear Translocation of NF-κB

NF-κB is a key regulator of proinflammatory factor expression in macrophages. We then detected the effect of AIBP on nuclear translocation of NF-κB after treatment of THP-1 cells with LPS. As shown in Figure 2A and B, AIBP could significantly prevent NF-κB nuclear translocation. However, AIBP did not effect the IL-1β-induced NF-κB nuclear translocation (Figure 2C, D). Taken together, these results suggest that AIBP might prevent LPS-induced macrophage inflammation by inactivating the NF-κB pathway.

AIBP Inhibits the Activation of Mitogen-Activated Protein Kinases (MAPKs)

MAPKs are important upstream regulators of the NF-κB signaling pathway in inflammatory and immune responses. As shown in Figure 3, AIBP could prevent the activation of MAPKs including p38 MAPK (p38), extracellular-signal regulated kinase (ERK) and c-Jun N-terminal kinase (JNK). The results suggest that AIBP inactivates NF-κB and reduces inflammation likely through suppressing the MAPK activation.

Effect of AIBP on MyD88 and TLR4 Expression

TLR4, a known activator of MAPKs, plays an important role in innate immune signaling. Activation of TLR4, the main receptor for bacterial LPS, is associated with lipid-induced inflammation. As the major adaptors of TLR4, myeloid differentiation factor 88 (MyD88)
AIBP Decreases Inflammation in an ABCA1-Dependent Manner

To determine the role of ABCA1 in AIBP-mediated inhibition of inflammation, we knocked-down the expression of ABCA1 in THP-1 macrophages (Figure 6A, B). After ABCA1 was silenced, AIBP did not lower inflammatory factor secretion (Figure 6C, D) and affect the localization of TLR4 in lipid rafts (Figure 6E, F), suggesting that AIBP alters lipid rafts and affects TLR4 in the cell membrane to decrease inflammation through the mechanism involving ABCA1.

Discussion

Atherosclerosis and the subsequent pathological changes are caused by lipid metabolism disorder and chronic inflammation of blood vessels, and is an important cause of CAD, myocardial infarction, stroke, peripheral arterial disease and other vascular events. Innate immunity plays an important role in the development of atherosclerosis. Monocytes/macrophages are the main immune cells of the innate immune response and have the promoting effect on the development of atherosclerosis. In this study, we reported that AIBP inhibits macrophage innate immunity by binding to apoA-1 (Figure 7), suggesting its potential role in prevention and treatment of atherosclerosis.

ApoA-I exerts anti-inflammatory effects by transporting cholesterol out from the cells and binding it with the MAPKs and NF-κB to induce inflammation. Our results showed that AIBP decreased MyD88 expression (Figure 4A). However, AIBP did not have any effect on TLR4 expression at both mRNA and protein levels (Figure 4B–D). Further study revealed that AIBP reduced the TLR4 level on the cell surface (Figure 4E, F), suggesting that AIBP-induced cholesterol efflux alters the abundance of TLR4 in the cell membrane. In addition, we used TLR4 siRNA to knock down its protein expression (Figure 4G, H), and then tested the expression of inflammatory factors in the presence of LPS (Figure 4I, J). The results showed that AIBP did not significantly affect LPS-induced secretion of inflammatory factors when TLR4 was downregulated, suggesting the anti-inflammatory action of AIBP was mainly dependent upon TLR4.

ABCA1-mediated cholesterol efflux from the cell membrane, which disrupts the plasma membrane lipid raft (cholesterol-rich membrane microdomains), has been found to affect signaling on the membrane receptor. We have demonstrated that AIBP could increase the ABCA1 expression and the cholesterol efflux via binding to apoA-I. We then determined whether AIBP could affect lipid raft in the plasma membrane. Cholera toxin B-marked lipid rafts were significantly reduced after AIBP treatment (Figure 5A, B). Lipid rafts were then extracted from THP-1-derived macrophage cell membranes by discontinuous density gradient ultracentrifugation. We observed that AIBP plus apoA-1 treatment, similar to methyl-β-cyclodextrin (MβCD), decreased the abundance of TLR4 in the lipid raft fraction (Figure 5C, D). However, AIBP(Δ115-123) did not affect the distribution of TLR4 on lipid rafts. These results suggest that AIBP decreases inflammation through the TLR4–MyD88-dependent pathway.

Figure 7. Schematic illustration of the effects of AIBP on ABCA1-dependent cholesterol efflux and TLR-4/NF-κB pathway-mediated inflammation. The present study has unraveled the following mechanisms: AIBP inhibits inflammatory signaling pathways through binding to apoA-1 and stabilizing ABCA1, and subsequent alteration of lipid rafts and TLR4 in the cell membrane, the decreasing TLR4 then inhibited the MAPKs phosphorylation and NF-κB nuclear translocation. Abbreviations as in Figures 1–4, 6.
ABCA1.4,24 AIBP could promote apoA-I binding to ABCA1 in macrophages.12 Thus, we speculated that the combination of AIBP and apoA-I may modulate inflammatory responses by influencing inflammatory signaling pathways. TLR4, an important receptor protein of LPS, plays an important role in mediating inflammatory signaling pathways and influences the development of cardiovascular diseases.25 We showed that AIBP did not have an effect on TLR4 expression at both mRNA and protein levels, but decreased the abundance of TLR4 in the cell membrane. These results were consistent with the effect of apoA-I on TLR4 in 3T3-L1 cells.44 Recruitment of TLR4 into lipid rafts is critical for the inflammatory response induced by LPS.25 In this study, AIBP could decrease the content of lipid rafts marked by CTB and increase the recruitment of TLR4 into lipid rafts. To sum up, AIBP alters the lipid raft content of macrophages by modulating ABCA1-mediated cholesterol efflux, reducing the amount of TLR4 into cell membrane lipid rafts, and then inhibiting inflammatory responses.

MyD88, an adaptor of TLR4, can activate signaling pathways downstream of members of the TLR and IL-1 receptor families, leading to activation of the pathways including NF-κB and MAPKs.27 NF-κB is an important transcription factor that regulates the expression of inflammatory factors and plays important roles in various stages of atherosclerosis.28 In response to an inflammatory stimulus, such as LPS, the NF-κB p65 subunits translocate to the nucleus where they increase transcription of inflammatory genes, such as MCP-1 and IL-6.30 In the present study, we showed that AIBP could inhibit activation of NF-κB and the secretion of TNF-α, IL-6, MCP-1, and IL-1β, suggesting an important role for NF-κB in AIBP inhibition of inflammation. MAPK signaling cascades likely play an important role in the pathogenesis of atherosclerosis.31 Our research revealed that AIBP can significantly inhibit the LPS-mediated phosphorylation of ERK, JNK, and p38. Taken together, AIBP inhibits the LPS-induced inflammatory response of macrophages via inactivation of NF-κB and MAPK signaling pathways.

ABCA1 may be involved in inflammatory regulation through several inflammatory signaling pathways.32,33 The interaction of apoA-1 with ABCA1 expressed in macrophages suppressed the ability of LPS to induce the expression of the inflammatory cytokines, which was reversed by silencing STAT3 or ABCA1.33,34 We previously demonstrated that apoA-1 suppresses CD40 proinflammatory signaling by preventing TRAF6 translocation to lipid rafts through ABCA1-dependent regulation of free cholesterol efflux.35 Downregulation of ABCA1 by siRNA abolished the activation of endothelial nitric oxide synthase (eNOS) and heme oxygenase-1 (HO-1) triggered by the apoA-1 mimetic peptide, D-4F, in endothelial cells.36 However, whether AIBP regulates the inflammatory response mediated by STAT3, CD40, eNOS, HO-1 or other signaling pathways remains to be further investigated.

We demonstrated that the effects of AIBP on TLR4, MyD88, NF-κB and MAPK signaling pathways were apoA-1- and ABCA1-dependent in human monocyte-derived macrophages. The effects were consistent with the findings by Wu et al37 who found that apoA-1 decreases TLR2 and NF-κB activation in an ABCA1-dependent manner in macrophages. In 3T3-L1 adipocytes, however, the inhibitory effects of apoA-1 on the LPS-induced nuclear localization of the NF-κB p65 subunits and MAPK signaling pathways were independent of ABCA1.4 The reason for this discrepancy remains unknown and may be related to different cell lines.

AIBP has a Rossmann-like fold located in a YjeF_N domain, which is a crucial domain for the protein family involved in cholesterol processing and steroid hormone metabolism. Previously, we demonstrated that AIBP 115-123 amino acids, localized in the Rossmann-like fold, are at least partially responsible for its binding to apoA-1.14 In this study, we found that AIBP could not suppress the secretion of inflammatory factors in the AIBP(A115-123) group. Furthermore, the effect of AIBP on NF-κB and MAPK signaling pathways was also abolished when amino acids from 115 to 123 were absent. These results showed that AIBP inhibits inflammatory signaling pathways by binding to apoA-1 in THP-1 macrophages.

In conclusion, this report provides new insights into the mechanisms for AIBP to suppress the inflammatory factor secretion in macrophages. Given that AIBP inhibits cholesterol efflux and foam cell formation, it is possible that AIBP may be a potential novel promising therapeutic strategy to inhibit inflammation and lipid accumulation in macrophages, thereby decreasing the development of atherosclerosis.
