Subclavian Steal Syndrome as a Common Denominator of Both Acute Coronary Syndrome and Ipsilateral Transient Ischemic Attack

Andreas Mitsis, MD; Xun Yuan, MD; Christoph A. Nienaber, MD, PhD

An 82-year-old man was admitted with recurrent angina and transient cerebrovascular ischemic attack (TIA) with ipsilateral (left-sided) hemianopia, associated with temporary dizziness without ischemic lesion on computed tomography. Coronary artery bypass grafting with left internal mammary artery (LIMA) to the left anterior descending artery (LAD) had been performed 18 years previously, and endovascular aneurysm repair 6 years prior to that. Electrocardiography showed sinus rhythm and ST-T depression in the V2–V6 leads, prompting coronary angiography that showed occlusion of the LAD, a patent LIMA and a 70% left subclavian artery (LSA) stenosis proximal to the LIMA graft. Given that the subclavian stenosis impacted on both the left vertebral artery (perfusing the cerebrum) and LIMA graft (perfusing the anterior myocardium) it was decided to proceed with ad hoc direct stenting of the LSA using an 8-mm×20-mm bare metal stent (Figure A,B). ST-T abnormalities normalized immediately after the procedure, allowing the patient to be discharged 2 days later. Twenty-four months after the intervention, the patient remained symptom free with regards to both cerebral and myocardial perfusion. Doppler flow examination confirmed reversal of pre-interventional subclavian steal, a phenomenon causing reversed flow from the ipsilateral posterior cerebral circulation and impaired anterior myocardial perfusion via the LIMA. In the present case, stenting of the LSA stenosis had re-established antegrade flow to both the left vertebral artery (posterior cerebral circulation) and to the anterior myocardium via the LIMA (Figure C,D). Appreciation of the pathophysiological complexity and advanced interventional skills are required for proper management in the context of acute coronary syndrome and simultaneous ipsilateral TIA.
