Long-Term Myocardial Damage in Peripartum Cardiomyopathy Associated With Myocarditis

Hiroaki Kawano, MD; Tomayoshi Hayashi, MD; Yuji Koide, MD; Koji Maemura, MD

A 54-year-old-Japanese woman had developed peripartum cardiomyopathy (PPCM) after her third delivery at the age of 43 years. Ultrasound echocardiography (UCG) showed diffuse hypokinesis of left ventricle (LV) with an ejection fraction (LVEF) of 19%. Endomyocardial biopsy showed mild cell infiltration and fibrosis (Figure A–C). On immunohistochemical staining there were more T cells (mainly CD8-positive T cells) than B cells (Supplementary Figure). Thus, she was diagnosed with PPCM related to lymphocytic myocarditis. Cardiac magnetic resonance imaging (MRI) demonstrated late gadolinium enhancement (LGE) in the LV (Figure D). One year after treatment with β-blocker, angiotensin II receptor blocker, and spironolactone, UCG indicated an LVEF of 56%, and MRI LGE was decreased (Figure E). Since then, her condition had been stable under treatment with no further pregnancies. Eleven years after the onset of PPCM, cardiac MRI showed a similar level of LGE to that in the second MRI (Figure F), and LVEF was 55% on UCG. Although MRI LGE is uncommon in PPCM,1 positive LGE and amelioration but continuation of regional LGE (myocardial damage) may be one of the characteristics of PPCM associated with myocarditis.

Figure. Endomyocardial biopsy showed (A) fibrosis (azan staining) and (B, C) mild cell infiltration (B, hematoxylin-eosin; C, leukocyte common antigen immunostaining). (D–F) Time course on cardiac magnetic resonance imaging: late gadolinium enhancement (arrows) in the left ventricle (D) on admission; (E) 1 year later; and (F) 11 years later.
