A novel bis(L-carnitinato)Zn(II) complex, Zn(car)2Cl2, was prepared, and its insulinomimetic and antidiabetic activities were examined. The complex showed a tendency to lower the high blood glucose levels of KK-Ay mice with type 2 diabetes mellitus when given by oral administration at a dose of 20 mg Zn/kg body weight for 16 d. In addition, the complex improved glucose tolerance ability when examined by the oral glucose tolerance test (1 g glucose/kg body weight).

Key words zinc(II) complex; L-carnitine; hypoglycemic effect; glucose tolerance test; type 2 diabetes; oral administration

Recently, both Zn(II) ion and several Zn(II) complexes have been found to have insulinomimetic activity.11 We reported that Zn(II) complexes with nicotinamide, maltol, amino acids, picolinic acid, picolinamide, and their derivatives have high insulinomimetic activities in in vitro and in vivo studies.2–7 However, these complexes were effective in showing the lowering effect of blood glucose by daily intraperitoneal injections to type 2 diabetes mellitus. When aiming at the clinical use of the complexes, it is essentially important to find complexes that are effective on oral administration. During the investigation for developing orally active insulinomimetic Zn(II) complexes, we found that a Zn(II) complex with L-carnitine ((R)-3-hydroxy-4-(trimethylammonio)butanoate : car) improves type 2 diabetes mellitus in mice when administered orally.

L-Carnitine is known to be a vitamin-like nutrient (Vitamin Bt) found in the heart, brain, and skeletal muscles8–10 It was reported that L-carnitine is incorporated in the body through the carnitine transporter.11,12 Its primary physiological role is to transport fatty acids across the cell wall into the mitochondria to provide the heart and skeletal cells with energy.13 In in vitro studies, it was reported that L-carnitine reverses much of the damage inflicted on the brain by free radicals.14 L-Carnitine has been used as a supplement which maintains physical stamina and promotes weight loss.15 On the other hand, the body uses L-carnitine to produce the enzyme, acetyl-L-carnitine transferase, which boosts choline metabolism and releases acetylcholine in the brain.16,17

We synthesized the complex, Zn(car)2Cl2, by the following method. To an aqueous solution of L-carnitine (30 mmol), an aqueous solution of ZnCl2 (15 mmol) was added and stirred for 0.5 h at room temperature. After the solution was uniform, the solvent was evaporated under the reduced pressure. The obtained oily residue was dissolved with ethanol and the solution was evaporated under the reduced pressure. The obtained powder was filtered off, washed with ethanol, and dried in vacuo. Yield: 63%. Anal. Found (%): C, 35.73; H 6.78; N 5.70. Calcd (% for Zn(C15H27NO3)2Cl2·0.5H2O; C, 35.95; H 6.68; N 5.99. IR (KBr disk): 1610 cm–1 for v(C=O) mp 83–90°C. [z]D20 +3.2° (H2O). On the other hand, IR spectra of the C=O stretching with L-carnitine at 1601 cm–1 have shifted to higher frequencies, 1610 cm–1 (v(C=O = For Zn(car)2Cl2). Therefore, we estimated the structure of Zn(car)2Cl2 as shown in Fig. 1.

The insulinomimetic activity of the complex was evaluated by using the isolated rat adipocytes treated with epinephrine in terms of the inhibition of free fatty acid release.18,19 The inhibitory effect of Zn(car)2Cl2 was compared with those of VOSO4 and ZnSO4 as positive controls (Fig. 2).

The effects of the three compounds were dose-dependent in the concentration range of 10–4–10–3 M. From these results, the apparent IC50 value, a 50% inhibitory concentration of the FFA released in each complex, was estimated to be 0.80±0.05 mM for Zn(car)2Cl2. Zn(car)2Cl2 was found to be more active than VOSO4 (IC50=1.00±0.08 mM) and to have almost the same activity to that of ZnSO4 (IC50=0.81±0.10 mM). In our previous research, if IC50 value of the VO compounds were equal to or less than 1.00 mM, the compounds showed antidiabetic activity by oral administration.11 In this study, we tested the Zn(II) complex by oral administration.

We evaluated the in vivo blood glucose lowering effect of Zn(car)2Cl2 in KK-Ay mice (22 weeks old: CREA Japan Inc., Tokyo) with type 2 diabetes mellitus. In this study, we used KK-Ay mice at the age of 22 weeks old because the blood glucose levels of old diabetes patients were reduced by administration of bovine prostate powder supplemented with Zn.20 They received oral administration of the complex daily at about 10:00 a.m. for 16 d. Blood samples were obtained from the mouse-tail vein, and the glucose levels were measured with a Glucocard (Arkray, Kyoto). The body weights of KK-Ay mice, which were allowed free access to solid food

(CREA Japan Inc.) and tap water, were measured daily during the administration of Zn(car)₂Cl₂. The intakes of solid food and drinking water for each mouse were checked daily throughout the experiments. When the mice were given Zn(car)₂Cl₂ at a dose of 20 mg Zn/kg body weight, they had a tendency to lower the blood glucose levels during the complex administration for 16 d (Fig. 3 left). The body weight of the KK-A⁺ mice in each group decreased slightly (Fig. 3 right). Also, due to the improvement of the blood glucose level of the KK-A⁺ mice treated with the Zn(car)₂Cl₂ by daily oral administrations at the dose of 20 mg Zn/kg for 16 d, the KK-A⁺ mice received the oral glucose tolerance test. As shown in Fig. 4, the blood glucose levels of the KK-A⁺ mice treated with t-carnitine were elevated to the maximum (520 mg/dl =28.9 mmol/l) at 30 min after the glucose administration, and then gently decreased. In contrast, the blood glucose levels of the KK-A⁺ mice treated with Zn(car)₂Cl₂ were also elevated (304 mg/dl =16.9 mmol/l) for 30 min, however, they were obviously lowered when compared with those of the KK-A⁺ mice treated with t-carnitine. The area under the curves (AUC) of the blood glucose in the level were calculated from the data in Fig. 4, being estimated to be 690±154, 789±184 and 431±216 mg/dl for the control KK-A⁺ mice, KK-A⁺ mice treated with t-carnitine, and KK-A⁺ mice treated with Zn(car)₂Cl₂, respectively (* significance at p<0.05 vs. the KK-A⁺ mice treated with t-carnitine (by Student’s t-test)). These results strongly indicated that the treatment of Zn(car)₂Cl₂ improves type 2 diabetes mellitus in KK-A⁺ mice by oral administration.

The proposed Zn(car)₂Cl₂ is assumed to be incorporated in the body through the carnitine transporter. Previously, Shisheva et al. have reported that a high dose of ZnCl₂ (210 mg Zn/kg body weight) stimulates the glucose uptake in rat adipocytes and reduces blood glucose concentration as much as 50% when was given orally to STZ rats. In contrast, Zn(car)₂Cl₂ at a low dose (20 mg Zn/kg body weight) was effective in lowering the blood glucose concentration orally administered.

In conclusion, Zn(car)₂Cl₂ has been found to have the in vitro insulinomimetic activity and in vivo blood glucose lowering effect, the improvement of the diabetes being supported by the results of the glucose tolerance test. The present result is the first example for the orally active Zn(II) complex. A detailed study about the mechanism of Zn(car)₂Cl₂ is now under way. The obtained results will be useful when they are clinically used on type 2 diabetes mellitus in the future.

The authors are grateful to the members of the analytical center of Osaka City University for elemental analyses.
