Received December 27, 2006; accepted February 16, 2007

A new biflavonoid, 2,3-dihydro-4′,4″-di-O-methylamentoflavone (5), and five known compounds, (−)-catechin (1), quercetin (2), 2,3-dihydrosciadopitysin (3), sciadopitysin (4), and isoginkgetin (6), were isolated from Podocarpus macrophyllus var. macrophyllus (Podocarpaceae). These compounds were evaluated their ability to inhibit cellular tyrosinase activity and for their melanin inhibitory activity in human epidermal melanocytes (HEMn). In the melanin synthesis assay, 2,3-dihydro-4′,4″-di-O-methylamentoflavone (5) showed a potent anti-tyrosinase effect with IC₅₀=0.098 mM in HEMn. It also significantly decreased both protein and mRNA levels of the tyrosinase-related protein-2 (TRP-2) by Western blot and quantitative real-time PCR (qRT-PCR) analysis. These findings suggest that the new compound, 2,3-dihydro-4′,4″-di-O-methylamentoflavone (5), is the most active component of P. macrophyllus var. macrophyllus in inhibiting pigmentation and that this inhibition is exerted through inhibition of transcription of the genes encoding TRP2.

Key words 2,3-dihydro-4′,4″-di-O-methylamentoflavone; human epidermal melanocyte; tyrosinase; tyrosinase-related protein-2; quantitative real-time PCR

Pigmentation due to the synthesis and dispersion of melanin protects the skin from harmful effects of sunlight,1 but unwanted hyperpigmentation can also produce a significant psychological stress. The development of effective therapies to modulate skin pigmentation has been slow owing to the complexity of molecular mechanisms regulating pigmentation.2 Our laboratory has determined that certain natural products inhibit tyrosinase, the key and the rate-limiting enzyme in the biosynthesis of melanin in pigmented cells of humans and animals.3 Tyrosinase (EC 1.14.18.1) is a monophenol or o-diphenol oxidoreductase. It is also known as polyphenol oxidase (PPO). This enzyme is a bifunctional copper-containing enzyme present in microorganisms, plants, and animals.3 It catalyzes two distinct reactions of melanin synthesis: the hydroxylation of tyrosine to 3,4-dihydroxyphenylalanine (DOPA) and the oxidation of DOPA to dopaquinone.4 After spontaneous conversion of dopaquinone to dopachrome, dopachrome tautomerase (tyrosinase-related protein-2, DCT/TRP-2) catalyzes the conversion of dopachrome to 5,6-dihydroxyindole-2-carboxylic acid (DHICA). Subsequently, the oxidative polymerization of DHICA is catalyzed by DHICA oxidase (tyrosinase-related protein-1, TRP-1).6 In mammals, melanin production is restricted to the melanocytes of the skin, hair follicles, and pigment epithelium in the retina. Three melanocyte-specific enzymes, tyrosinase, TRP-1, and TRP-2 are involved in melanogenesis, in which tyrosine is converted into melanin pigments.7 The tyrosinase-related proteins, TRP-1 and TRP-2, catalyze distal steps that control the type of melanin produced.8−10 Tyrosinase inhibitors may be potential skin whitening agents in the development of medical and cosmetic products against hyperpigmentation.11

Podocarpaceae are mainly distributed in the Southern hemisphere, such as South America and Australia, and in parts of the Northern hemisphere, including southeastern China, Taiwan, Japan, and the Philippines. Podocarpus macrophyllus (THUNB.) S. WEET var. macrophyllus grows in Taiwan, southeastern China, and Japan, and is usually used as a tree and as a decoration plant because of its beautiful shape. Conifers have evolved constitutive and inducible defense mechanisms for wound healing and against the attack of bark beetles and other organisms.11 Previous investigation of Podocarpus species afforded flavonoids, diterpenoids, and steroids.12−17 An ethanolic extract of P. nerifolius showed antiproliferative activity against two major tumor cell lines.18 There is not yet a published study of the constituents of P. macrophyllus var. macrophyllus and its related activities. In the present study, we evaluated the effect of constituents from this plant on the pigmentation and that this inhibition is exerted through inhibition of transcription of the genes encoding TRP2.

Results and Discussion

The 80% aqueous MeOH extract of P. macrophyllus var. macrophyllus was fractionated with EtOAc. The two fractions were chromatographed over Diaion HP 20, ODS, and Sephadex LH-20 columns, then purified by reverse-phase HPLC to yield six compounds. The structures of the known compounds were elucidated by comparing their physical properties with reported data. Compounds 1−6 were characterized as (−)-catechin (1),19 quercetin (2),20 2,3-dihydrosciadopitysin (3),21 sciadopitysin (4),22 the new amentoflavone derivative (5), and isoginkgetin (6) (Fig. 1).23 Compound 5 was obtained as a pale-yellow powder. The HR-FAB-MS displayed a quasi-molecular ion at m/z 569.1436 [M+H]+ suggesting a molecular formula of...
C32H24O10. The UV spectrum of compound 5 exhibited absorption maxima at 370 nm and 265 nm. In the 1H-NMR spectrum of compound 5, two chelated hydroxyl groups had resonances at δ 12.16 (1H, br s) and 13.08 (1H, br s) and two O-methyl groups had resonances at δ 3.78 and 3.85 (each 3H, s). The resonances at δ 5.94 and 5.97 (each 1H, br s) were ascribable to H-6 and H-8 on the I-A ring, respectively, those at δ 5.57 (1H, dd, J=2.6, 12.8 Hz, H-2), 3.27 (1H, m, H-3a), 2.81 (1H, m, H-3b) arose from the I-C ring, and the 13C-NMR resonances at δ 79.4 (d, C-2) and 43.2 (t, C-3) indicated the presence of a flavanone unit. Furthermore, the flavone unit in compound 5 was similar to that in compound 3 on the basis of resonances observed at δ 6.67 (1H, s, H-3a) and 6.41 (1H, s, H-6a), as well as on AA’XX’ system resonances at δ 7.67 (2H, d, J=8.7 Hz, H-2′ and H-6′) and 6.98 (2H, d, J=8.7 Hz, H-3′ and H-5′). The characteristics of the 13C-NMR spectrum of compound 5 (Table 1) were similar to those of biflavonoids 3, 4, and 6. Thus, compound 5 was composed of a flavanone and a flavone unit. Two O-methyl groups [δ163.1 (H-5) and δ163.9 (H-4)] in compound 5 linked to C-4′ and C-5′, respectively, were revealed by the HMBC spectrum. The linkage between C-3′ of the flavanone unit and C-8′ of the flavone unit was confirmed by HMBC and NOESY spectra. The HMBC spectrum demonstrated that H-2′ ([δ 7.62 (1H, d, J=1.6 Hz)] was related to C-2 (δ 79.4) and C-8′ (δ 104.8) and that H-6′ [δ 6.41 (1H, s)] was related to C-5′ (δ 162.0), C-8′ (δ 104.8) and C-10′ (δ 105.2). The heteronuclear correlations further established the constitution of compound 5: H-2/C-1′, H-2/C-6′, H-3a/C-4′, H-3b/C-4′, H-6/C-5′, H-6/C-7′, H-8/C-9′, H-8/C-10′, H-5′/C-3′, H-5′/C-4′, H-6′/C-2′, H-6′/C-4′, H-3′/C-2′, H-3′/C-4′, H-3′/C-10′, H-3′/C-1′, CH3O-4/C-4′, and CH3O-4′/C-4′ (Fig. 2). The NOESY spectrum showed the correlation between H-2 and H-3, H-2 and H-2′, H-2 and H-6′, H-3 and H-2′, H-5′ and H-6′, as well as H-5′ and –OMe for the flavanone unit. For the other flavone unit, H-3′ was correlated with H-2″, H-2′″ with H-3″, and H-3″ with –OMe. The coupling constant of H-2 (J=2.6, 12.8 Hz) indicated the equatorial location of aryl group on C-2 and was further confirmed by comparing the CD spectrum with literature values for flavanones. It showed a positive Cotton effect at 328 nm (π→π*) and a negative Cotton effect near 292 nm (n→π*). Thus, compound 5 with a 2S configuration exhibited a conformation with a C-2 equatorial aryl group. Accordingly, compound 5 was determined to be 2,3-dihydro-4′,4″-di-O-methylamentoflavone (5) (Fig. 2). To our knowledge, this is the first reported isolation of 2,3-dihydrobiflavones, biflavones, and flavones from *P. macrophyllus* var. *macrophyllus*.

The Effects of Anti-tyrosinase Activities and Melanin Inhibition of the Isolated Constituents in HEMn Cells

Tyrosinase activity is involved in the formation of melanin...
pigments. Compounds exhibiting tyrosinase inhibitory effects may reduce melanin biosynthesis and may find some applications in cosmetic products. In the present study, each isolated component was evaluated for its effect on the cell viability of HEMn cells. When the concentration was 100 μM, there most certainly would not be any synthesis of melanin in mammalian melanocytes. TRP-1 was reported to be involved in the maintenance of melanosome ultrastructure, and to affect melanocyte proliferation, morphology, and melanocyte cell death. 2,3-Dihydro-4′,4″-di-O-methylamentoflavone (5) showed the most effect (Table 2). Its tyrosinase inhibition was shown in the concentration-dependent manner ranging from 0.04 to 0.1 mM, and its IC_{50} was 0.098 mM (compare with the positive control arbutin [IC_{50} 3.0 mM]).

Besides tyrosinase, two tyrosinase-related proteins, TRP-1 and TRP-2, have been characterized and shown to catalyze specific reactions in melanin synthesis. The effect of 2,3-dihydro-4′,4″-di-O-methylamentoflavone (5) on the expression of these tyrosinase-related proteins was evaluated by Western blotting. Treatment with various concentrations (0.04 mM, 0.05 mM, 0.06 mM, and 0.1 mM) for 24 h did not noticeably influence the expression TYR and TRP-1 proteins but strongly inhibited the expression of TRP-2 protein (Fig. 3). Tyrosinase is the key enzyme in pigment synthesis. The essential function of tyrosinase in melanin biosynthesis has been known for many decades; in the absence of functional tyrosinase, there most certainly would not be any synthesis of melanin in mammalian melanocytes. TRP-1 was reported to play an important role in the stabilization of tyrosinase, to be involved in the maintenance of melanosome ultrastructure, and to affect melanocyte proliferation, morphology, and melanocyte cell death. 2,3-Dihydro-4′,4″-di-O-methylamentoflavone (5) showed the most effect (Table 2). Its tyrosinase inhibition was shown in the concentration-dependent manner ranging from 0.04 to 0.1 mM, and its IC_{50} was 0.098 mM (compare with the positive control arbutin [IC_{50} 3.0 mM]).

### Fig. 3. Expression of Tyrosinase-Related Proteins in 2,3-Dihydro-4′,4″-di-O-methylamentoflavone (5)-Treated HEMn

Cultured melanocytes were treated with medium or test compounds for 24 h. The extent of reduction in melanin content following treatment with these substances varied with the component. 2,3-Dihydro-4′,4″-catechin (1), 2,3-dihydro-4′,4″-di-O-methylamentoflavone (5), and isoginkgetin (6) showed less toxicity in HEMn cells (>80% viability) (Table 2). We further tested the inhibitory activities of the three compounds on cellular tyrosinase. Of these three, 2,3-dihydro-4′,4″-di-O-methylamentoflavone (5) was the most potent inhibitor of tyrosinase at 0.1 mM (53.2% inhibition). The extent of reduction in melanin content following treatment with these substances varied with the component. 2,3-Dihydro-4′,4″-di-O-methylamentoflavone (5) also showed the most effect (Table 2). Its tyrosinase inhibition was shown in the concentration-dependent manner ranging from 0.04 to 0.1 mM, and its IC_{50} was 0.098 mM (compare with the positive control arbutin [IC_{50} 3.0 mM]).

### Fig. 4. Expression of TYR and TYRP2 mRNAs in 2,3-Dihydro-4′,4″-di-O-methylamentoflavone (5)-Treated HEMn

Cultured melanocytes were treated with medium or test compounds for 24 h. TYR and TYRP2 mRNA expression was normalized to the expression of GAPDH mRNA. Measurements were conducted in triplicate, and mean expression values for test samples relative to mean expression values for negative controls are indicated: C: medium only; A: arbutin at 2.5 mM, 1: (5) at 0.04 mM, 2: (5) at 0.08 mM, 3: (5) at 0.06 mM, 4: (5) at 0.04 mM. Statistical significance (p-value <0.05) was tested using the non-parametric Mann–Whitney U-test.
been isolated from *P. macrophyllus* var. *macrophyllus* for the first time. These six compounds had different cellular tyrosinase inhibitory activities. Among these compounds, 2,3-dihydro-4,4′-di-O-methylmentoflavone (5) had the downregulated the protein and mRNA expression of the pigment-related enzymes, tyrosinase and TRP-2. Thus, this compound is the most attractive of the six candidate additives for the cosmetic products.

**Experimental**

**Materials** Arbutin, HEPEs buffer, 6-hydroxy-2,5,7,8-tetramethylchroman-2-carboxylic acid (Troclox), 3-(4,5-dimethyl-thiazol-2-yl)-2,5-diphenyl-
tetrazolium bromide (MTT), DOPA, phosphate-buffered saline (PBS), and phenylmethylsulfonyl fluoride (PMSF) were purchased from Sigma-Aldrich Chemical Co. (St. Louis, MO, U.S.A.). The other chemcials or reagents used in the study were high-grade commercial products.

**Plant Material** The leaves of *P. macrophyllus* var. *macrophyllus* were collected in August 2003 in Taipei, and identified by Dr. Kur-Ta Cheng, Department of Biochemistry, Taipei Medical University, Taiwan. A voucher specimen (M-63) is deposited at the Graduate Institute of Pharmacognosy, College of Pharmacy, Taipei Medical University, Taipei.

**General Experimental** 1H- and 13C-NMR spectra were recorded on a Bruker DRX-500 MHz (1H at 500 MHz; 13C at 125 MHz), and chemical shifts were given in δ (ppm) with TMS as an internal standard. 2D spectra were determined by 1H-1H COSY, HMOC, HMB, and NOESY experiments. Optical rotation was measured on a JASCO P-1020 polarimeter (Tokyo, Japan). HPLC was carried out with a Hitachi L-7100 pump and an L-7420 UV–VIS detector with a reversed phase column (Biosil ODS-W, 4.6 mm. i.d., 250 mm. Biotic Chemical, Taipei, Taiwan). UV spectra were recorded on a UV-1601 (Shimadzu, Tokyo, Japan) spectrophotometer. All solvents were distilled before use. Solvents were removed from the extracts by rotary evaporator under reduced pressure at temperatures up to 40 °C. TLC was performed on silica gel (Kieselgel 60 F 254, Merck, Darmstadt, Germany).

**Extraction and Isolation** The fresh leaves of *P. macrophyllus* var. *macrophyllus* (8 kg) were homogenized in 80% MeOH (∼3) at room temperature. After filtering and concentrating under reduced pressure, the 80% MeOH extract was obtained. A suspension of the 80% MeOH extract in H2O was partitioned with EtOAc to give EtOAc and aqueous fractions. The aqueous fraction was subjected to chromatographic separation over Diaion HP 20 and eluted with increasing MeOH concentration to give seven fractions (Frs. 1 to 7). Fr. 2 was rechromatographed over Sephadex LH-20 with 30% MeOH, and then purified by semi-preparative HPLC using 15% MeCN to give compound (2) (12 mg). The EtOAc layer was subjected to chromatographic separation over Sephadex LH-20 and eluted with MeOH to give six fractions (EA-Frs. 1 to 6) corresponding to the TLC results. EA-Fr. 3 was further chromatographed over an MCI CHP20P column with 80% MeCN and then purified by semi-preparative HPLC eluting with 65% MeCN to give compound 3 (6.5 mg). EA-Fr. 4 was purified by semi-preparative HPLC eluting with 65% MeCN to give compound 4 (7.3 mg). EA-Fr. 5 was rechromatographed over Sephadex LH-20 column with 100% MeOH and then purified by semi-preparative HPLC eluting with 65% MeCN to give compounds 5 (3.2 mg) and 6 (4.3 mg), respectively.

(−)-Catechin (1): A pale-yellow powder, mp 176 °C. [α]D 22 = −42.5° (c = 0.5, MeOH). The spectral data were compared with the literature. (21)

Quercetin (2): A yellow powder, mp 315 °C. FAB-MS m/z 303 [M+H]+. The physical and spectral data were compared with an authentic sample and published data. (20)

2,3-Dihydroxyisopimpinellin (3): A amorphous powder, ESI-MS m/z 583.3 [M+H]+. The spectral data were compared with the published data. (23)

Sciodipentin (4): A pale-yellow powder, ESI-MS m/z 581.3 [M+H]+. The spectral data were compared with the published data. (23)

2,3-Dihydro-4,4′-di-O-methylmentoflavone (5): A pale-yellow powder, [α]D 22 = −10° (c = 0.1, MeOH). UV λmax (EtOH) nm (ε): 280 (89125), 322 (501919). CD [MeOH, nm, Δε]: 292 (−22.2), 328 (+15.1). 1H-, 13C-NMR (Table 1). FAB-MS m/z 569.1 [M+H]+. High-resolution FAB-MS m/z 569.1436 [M+H]+ (Caled for C23H13O10, M 569.1448). 

Isoginkgetin (6): A pale-yellow powder, FAB-MS m/z: 567.1 [M+H]+. The spectral data were compared with the published data. (23)

**Cell Culture** Primary skin cells, HEMa (Cascade Biologies Inc., Portland, Ore, U.S.A.), from neonatal foreskin were cultured in Medium 254 (Cascade Biologies) supplemented with Human Melanocyte Growth Supplement (HMGs, Cascade Biologies).

**MTT Assay for Cell Viability** Cells were plated at 1×10⁴ cells (24-well plates). Twenty-four hours after plating, test samples were added and cultures were incubated for an additional 24 h. Viability was determined using the MTT method, a colorimetric assay involving formation of purple formazan by mitochondrial dehydrogenase of active mitochondria. Cell viability was calculated according to the equation:

\[
\text{cell viability} = \frac{\text{absorbance (sample tested)}}{\text{absorbance (medium only)}} \times 100\%
\]

**Assay of Cellular Tyrosinase Activity** Tyrosinase activity was measured as described previously with minor modifications. (24) HEMa cells were cultured in 24-well plates. After treatment with individual test samples for 24 h, the cells were washed with phosphate-buffered saline (PBS) and lysed with phosphate buffer, pH 6.8, containing 1% Triton X-100. The cells were disrupted by freezing and thawing, and lysates were clarified by centrifugation at 10000 g for 10 min. After determination of protein content with a Bio-Rad protein assay kit, lysates were adjusted with lysis buffer to contain equal amounts of protein (40 μg). These lysates were then added to wells (96-well plates) containing 2.5 μM l-DOPA and 0.1 μM phosphate buffer, pH 6.8. After incubation at 37 °C for 1 h, the absorbance of samples was measured at 475 nm using an ELISA reader. Tyrosinase inhibitory activity was calculated with the following formula:

\[
\text{tyrosinase inhibition} (%) = \frac{1 - (\text{absorbance (sample tested)} / \text{absorbance (control)})}{100\%}
\]

**Measurement of Melanin Content of Melanocytes** Melanin contents were measured as described previously with slight modifications. (25) Briefly, cells were treated with tested individual samples for 24 h. Cell pellets were dissolved in 1 N NaOH at 37 °C overnight and centrifuged for 10 min at 10000 g. The optical density (OD) of each supernatant was measured at 450 nm using an ELISA reader.

**Western Blot Analysis of the Tyrosinase-Related Proteins** Western blot analysis was performed as described previously to determine the expression of tyrosinase and TRPs. (26) Cells (1×10⁶/well) were lysed with PBS containing 1% Triton X-100, 1 mM phenylmethylsulfonyl fluoride (PMSF), 1 mg/ml aprotinin, and 10 mg/ml leupeptin, and lysates were subjected to centrifugation at 12000 g for 10 min. The total protein content of each supernatant was determined with a Bio-Rad protein assay kit. Equal amount protein content of each sample was added to SDS sample buffer, and proteins were separated by polyacrylamide gel (10%) electrophoresis. Following electrotransfer to PVDF membranes (Immobilon-P, Millipore Corp., Bedford, Mass, U.S.A.), the membranes were incubated overnight with PBS containing 5% non-fat dry milk, 0.1% Tween 20 and 0.1% NaCl. Anti-tyrosi-

neider (C-19), anti-TRP-1 (G-17), and anti-TRP-2 (D-18) antibodies (Santa Cruz Biotechnology Inc., Europe) were added at a 1:1000 dilution, and membranes were incubated at room temperature for 3 h. After extensive washes, the blots were incubated for 2 h at room temperature with alkaline phosphatase-conjugated anti-goat IgG (Santa Cruz Biotechnology) diluted 1:5000 in PBS containing 5% non-fat dry milk, 0.1% Tween 20, and 0.1% NaCl. After washing, protein-bound alkaline phosphatase activity was detec-
ted with NBT/5-bromo-4-chloro-3-indolyl phosphate (BCIP) substrate. The extent of protein loading was evaluated by Western blotting with an antibody to β-actin.

**RNA Extraction and Reverse Transcription** Total RNA was extracted using the High Pure RNA Isolation Kit (Roche Molecular Biochemicals, Mannheim, Germany). The quality of the total RNA sample was evaluated by determination of the OD260/OD280 ratio. To prepare a cDNA pool from each RNA sample, total RNA (1 μg) was reverse-transcribed using the Transcriptor First Strand cDNA Synthesis Kit (Roche Molecular Biochemicals) according to the manufacturer’s instructions. Each cDNA pool was stored at −20 °C until real-time PCR analysis was performed.

**PCR Primers** The specific oligonucleotide primer pairs used for quanti-
tific real-time PCR (qRT-PCR) were selected from the Roche Universal ProbeLibrary. The sequences of the proper primers are as follows: TYR, forward primer: 5′-CAGTCCTTCTCTTCTCCGAGA-3′, reverse primer: 5′-CCGCTGCATCCACGCAGCA-3′; TYRP1, forward primer: GCTTTT-GGACCATGGCCAGC, reverse primer: GGCTCTTGCAACATTTCCTG; TYRP2, forward primer: CGACTCTGATTCGGCAACTCA, reverse primer: GGTGGTTTGTAGTCATCCAAAGC; GAPDH, forward primer: AGC- CACATCGTCAGACAC, reverse primer: GCCCAATACGACCAAATCC.

**Quantitative Real-Time PCR (qRT PCR) Assay for Tyrosinase-Re-

land, Vol. 55, No. 5
References

Statistical Analysis

Differences between the groups were tested for significance by means of the non-parametric Mann–Whitney U-test. A p-value of <0.05 was considered to indicate statistical significance.

Acknowledgments

This study was supported by a grant from the Taiwan Salt industrial corporation. We are grateful to Shwu-Huey Wang (Instrumentation Center of Taipei Medical University) and Shou-Ling Huang (Nuclear Magnetic Resonance Lab, Instrumentation Center of Taipei Medical University) for recording circular dichroism data (School of Pharmacy, College of Science, National Taiwan University) and to Prof. Shoei-Sheng Lee for recording circular dichroism data (School of Pharmacy, College of Medicine, National Taiwan University). We also express our gratitude to the Juridical Person of the Yen Foundation, Taiwan, for supporting this study.
