Simple and mild Cu-mediated arylation of various amines by use of tetraarylantimony acetate (Ar₄SbOAc) is described. The Ullmann-type condensation of Ar₄SbOAc with aliphatic and electron rich aromatic amines proceeded efficiently in the presence of copper(II) acetate. The arylation can be carried out under aerobic conditions without care of exogenous oxygen. This simple procedure exceeds the conventional Ullmann condensation which often requires harsh reaction conditions.

Key words tetraarylantimony(V) acetate; *N*-arylation; Ullmann condensation; copper(II) acetate; aerobic reaction

The aryl–nitrogen bond can be found in a wide range of biologically active compounds such as bradykinin (BK) receptor antagonist martinellie acid¹⁾ and opioid receptor agonist CJ-15161.²⁾ Thus, it is desirable to develop simple and efficient methods for aryl–nitrogen bond formation. Among them, research on transition metal-catalyzed C–N bond formation has flourished recently. For example, remarkable progress in bulky and electron rich phosphine ligands has enabled Pd- and Ni-catalyzed cross-couplings of amines and alcohols with aryl halides and sulfonates.^{3,4)} These transition metal-catalyzed reactions have been recognized as one of the most reliable methods for C–N bond formation.^{5–8)} Direct C–H functionalization to form C–N bonds has also been another convenient entry for C–N cross-coupling using transition metal catalysts.^{9,10)} However, these elaborated catalysts and phosphine ligands often tend to be sensitive to air oxidation and hydrolysis by moisture. These problems make the traditional Ullmann condensation attractive in large and industrial scale applications employing low price, non-toxic, and air-stable Cu reagents.^{11–14)}

Because traditional Cu-mediated Ullmann condensation has been conducted and limited by harsh reaction conditions,¹⁵⁾ many improvements in Ullmann-type C–N bond formation have recently been made. For example, aryl halides employed as aryl donors in the traditional Ullmann condensation were replaced with highly reactive transmetallating agents such as organo-boron,^{13,14,16–19)} -silicon,²⁰⁾ -stannane,^{19,21)} -lead,^{14,22)} and -bismuth compounds.^{14,23–25)}

In the course of our studies on organoantimony (Sb) compounds as synthetic reagents, we have recently demonstrated that Sb(III) compounds were efficient transmetallating agents for transition metal-catalyzed cross-coupling reactions.^{26,27)} We also reported that Sb(V) compounds work as useful

pseudo-halides in Pd-catalyzed cross-coupling reactions.²⁸⁾ These results stimulated us to employ them in Cu-mediated arylation of amines.

As for Sb-mediated *N*- and *O*-arylation of amines and alcohols, triphenylantimony *ortho*-phenylenedioxi- des and triphenylstibane have been reported to function as aryl donors.^{29,30)} However, the reactions are not so efficient, in that they must be carried out using amines or alcohols as solvents at high temperature. Thus, we focused on highly reactive Sb(V) compounds as Cu-mediated *N*-arylating agents.^{31,32)}

To search for effective organoantimony compounds in Cu-mediated *N*-arylation of amines, we first investigated the reaction of various Sb(V) compounds (**1**–**5**) with *p*-toluidine (**6a**) in the presence of Cu(OAc)₂ under the conditions shown in Table 1. The reaction of Ph₅Sb (**1**) with **6a** resulted in the expected *N*-phenylation to afford *N*-phenyl-*p*-toluidine (**7a**) in 80% yield. However a considerable amount of homo-coupling product (**8**: 27% yield) was formed as a side product. Whereas treatment of **6a** with Ph₄SbOAc (**2**) gave **7a** in 84% yield and no noticeable formation of **8** was observed.³³⁾ When bromostiboranes (**3**, **4**) were employed in the present reaction, di(*p*-tolyl)diazene (**9**) was formed as a major product. The reaction by use of diacetate Ph₃Sb(OAc)₂ (**5**) instead of **2** was ineffective and afforded **7a** in 6% yield. It has been well documented that the Cu-mediated *N*- and *O*-arylation with arylboronic acids could be achieved effectively in the presence of an oxidizing agent or under aerobic conditions.^{13,14)} However, the reaction under oxygen atmosphere did not improve the yield of **7a** (67%). Similar reaction under argon atmosphere also gave **7a** in 70% yield.

We next searched for suitable Cu reagent, and the results are summarized in Table 2, entries 1–6. The divalent Cu-reagent Cu(OBz)₂ also promoted the *N*-arylation, but the yield of **7a** was unsatisfactory. It is noteworthy that monovalent CuOAc and Cu(I) thiophene-2-carboxylate (CuTC) were effective, giving rise to **7a** in acceptable yields. Addition of Cu powder also promoted the *N*-arylation, but stoichiometric amount of copper reagent is essential. We next attempted catalytic reaction by use of 0.3 eq Cu(OAc)₂ and found that the reaction afforded **7a** in 69% yield after 24 h at 40 °C. This result implies that the *N*-arylation proceeds under the catalytic

condition, however, the reaction requires longer reaction time and higher temperature to achieve satisfactory result. Thus, we decided to use 1.1 eq of Cu(OAc)₂ in the following experiments.

We next examined the effect of bases and the results are shown in Table 2, entries 7–12. The reaction proceeded without base, but the yield was lower than that in the presence of triethylamine (TEA). The reaction needs excess TEA (6.0 eq) for homogeneous reaction. When 3.0 eq of TEA was used in the present reaction, a part of Cu(OAc)₂ remains undissolved and the yield of **7a** decreased to 76% after 48 h (GC yield). Addition of di(isopropyl)amine promoted *N*-phenylation, while that of pyridine and DBU gave unsatisfactory results. It should be noted that bidentate amines such as TMEDA and 2,2'-bipyridyl completely suppressed the *N*-arylation. Search for a suitable solvent revealed that dichloromethane (88%, GC yield) was the optimal solvent; toluene (58%), 1,4-dioxane (25%), and acetonitrile (83%) led to inferior results. Consequently, the best result was obtained when the reaction was carried out by using Cu(OAc)₂ as a copper reagent (1.1 eq), TEA (6.0 eq) as a base, and dichloromethane as a solvent under atmospheric air. When a mixture of **2** and **6a** was heated at 40 °C for 6 h under the above optimal conditions, **7a** was isolated in good yield (84%). Thus, we performed the subsequent reactions at

Chart 1. Reaction of Tetraarylantimony Acetate (**10**, **11**) with **6a**

40 °C. In the reactions of tetrakis(4-methylphenyl)- (**10**) and tetrakis(4-chlorophenyl)antimony acetate (**11**) with **6a**, the expected *N*-arylated products, bis(4-methylphenyl)amine (**12**) and (4-chlorophenyl)(4-methylphenyl)amine (**13**) were isolated in good yields, respectively (Chart 1).³⁴⁾

Having the established reaction conditions, various amines (**6b–p**) were reacted with **2** (Table 3). Primary aliphatic amines gave the corresponding *N*-arylated product (**7b–d**) in moderate yields which could be improved by carrying out the reactions with 0.5 eq of Cu(OAc)₂. The results imply that these aliphatic amines were easily oxidized to form azo-compounds with excess Cu(OAc)₂.³⁵⁾ In the case of aromatic amines, a marked *p*-substituent effect was observed. The aromatic amines with an electron-donating *p*-methoxy group gave superior result to that with an electron-withdrawing *p*-nitro group. Sterically hindered *ortho*-substituted aniline derivatives (**6l**, **m**) and secondary amines (**6f**, **g**, **n**, **o**) also gave the corresponding *N*-arylated products in moderate yields ex-

Chart 2. Possible Mechanism

cept for *t*-butyl- (**6e**) and diphenylamines (**6p**). The fact that no formation of triphenylamine from **6p** is in good accordance with the observation that only mono-phenylated product of amines was formed in the present reaction.

Exact mechanism of this Sb-mediated *N*-arylation is unclear at present. We considered that a similar mechanism for diaryliodonium salts by Lockhart³⁶⁾ and for lead(VI)²²⁾ and bismuth(V)²³⁾ compounds by Barton *et al.* could be applicable to our Sb-mediated *N*-arylation (Chart 2).

The first step of the reaction would be the generation of Cu(I) species (**A**) by reduction of Cu(OAc)₂ with amine or excess TEA. The intermediate **A** thus formed reacts with amine to give Cu(I)L₂NHR (**B**). Oxidative addition of Ar₄SbOAc to **B** affords Cu(III) intermediate (**C**) which leads to Cu(III) complex (**D**) accompanied by elimination of Ar₃Sb. This intermediate (**D**) successively undergoes reductive elimination to give the final product (**E**) with regeneration of the Cu(I) species (**A**). As noted above, Ar₃Sb was formed during the course of this reaction, however, the formation of Ar₃Sb was not detected by GC analysis of the reaction mixture. This result would be explained that Ar₃Sb is easily oxidized to Ar₃SbO or Ar₃Sb(OAc)₂ by air or excess Cu(OAc)₂ in the reaction mixture. A similar reaction was observed in the *N*-arylation of amines²³⁾ and hydrazones²⁵⁾ by use of Ar₃Bi and Cu(OAc)₂.

In conclusion, we disclosed that hypervalent Ar₄SbOAc is a new *N*-arylating agent which can be used under mild conditions without special care of exogenous oxygen. We have also recently found that a similar *N*-arylation took place when a mixture of Ar₃Sb and amine (**6**) was heated with large excess (2.5–5 eq) of Cu(OAc)₂ in acetonitrile, however, the reaction requires a longer reaction time (6–24 h) at higher temperature (60–70 °C). The details including its reaction mechanism and further application of this simple and mild *N*-arylation will be discussed in due course.

- Typical procedure: To a solution of **2** (0.75 mmol), **6a** (0.5 mmol), and TEA (3.0 mmol) in CH₂Cl₂ (5 ml) was added Cu(OAc)₂ (0.55 mmol), and the mixture was stirred for 6 h at 40 °C (bath temperature). The mixture was diluted with CH₂Cl₂ (50 ml) and NH₃ aq. (1.5 mol/l, 50 ml) and then stirred for 30 min. The organic layer was separated, washed with brine and dried over anhydrous MgSO₄. After removal of the solvent *in vacuo*, the residue was separated by SiO₂ column chromatography (hexane : CH₂Cl₂ = 3 : 1) to give **7a** (77 mg, 84% yield).
- The tetraarylantimony acetates (**2**, **10**, **11**) were prepared by disproportionation reaction on heating 1 : 1 mixture of Ar₅Sb and Ar₃Sb(OAc)₂ in toluene (100 °C) for 3–6 h. **2**: (C₆H₅)₄SbOAc, mp 135–136 °C (lit.³⁷⁾ 129–131 °C), **10**: (4-CH₃C₆H₄)₄SbOAc, mp 160–163 °C (lit.³⁸⁾ 157–158.1 °C), **11**: (4-ClC₆H₄)₄SbOAc, mp 184–187 °C.
