Lignans from *Santalum album* and Their Cytotoxic Activities

Yukiko Matsuo* and Yoshihiro Mimaki

Tokyo University of Pharmacy and Life Sciences, School of Pharmacy; 1432–1 Horinouchi, Hachioji, Tokyo 192–0392, Japan. Received December 24, 2009; accepted January 19, 2010; published online January 21, 2010

A new neolignan, (7R,8R)-5-O-demethylbilagrewin (1), together with four known lignans (2—5), were isolated from the heartwood of *Santalum album* (Santalaceae). The structure of 1 was determined by analysis of extensive spectroscopic data. The isolated compounds and derivatives were evaluated for their cytotoxic activities against HL-60 human promyelocytic leukemia cells and A549 human lung adenocarcinoma cells. Compounds 1 and 2 exhibited cytotoxicity against HL-60 cells with IC₅₀ values of 1.5±0.02 and 4.3±0.13 μM, and against A549 cells with IC₅₀ values of 13.6±0.32 and 19.9±1.27 μM, respectively. The aldehyde group of 1 and 2 was revealed to be a structural requirement for the appearance of cytotoxicity in this type of lignans. These tumor cell deaths were shown to be mediated through induction of apoptosis.

Key words  *Santalum album*; Santalaceae; neolignan; apoptosis; HL-60 cell; A549 cell

*Santalum album* (L.) (Santalaceae) is a tropical evergreen tree that grows in India, Indonesia, Malaysia, and Australia. Sandalwood oil, which is obtained by steam distillation from the heartwood of *S. album*, is widely used as an aromatherapy as an antidepressant, anti-inflammatory, antifungal, astringent, sedative, insecticide, and lung antiseptic. Previous phytochemical studies on *S. album* have resulted in the isolation and identification of sesquiterpenes and aromatic compounds. In particular, α-santalol and β-santalol with various biological activities are known to be the main constituents of *S. album*. The present investigation of the heartwood of *S. album*, with particular attention paid to its aromatic compounds, led to the isolation of five lignans (1—5), including one new neolignan, (7R,8R)-5-O-demethylbilagrewin (1). This paper is a report on the structural determination of the new neolignan, and the cytotoxic activities of 1—5 against HL-60 human promyelocytic leukemia cells and A549 human lung adenocarcinoma cells. The apoptosis induction properties of the lignans with the cytotoxic potency are also described.

The heartwood of *S. album* (1.0 kg) was extracted with hot MeOH. The MeOH extract was passed through a porous-polymer polystyrene resin (Diaion HP-20) column, and the MeOH-eluted fraction was subjected to column chromatography (CC) using silica gel and octadecylsilanized (ODS) MeOH-eluted fraction was subjected to column chromatography on a polymer polystyrene resin (Diaion HP-20) column, and the MeOH eluate was subjected to reversed-phase preparative HPLC, giving compound 1—5 (Fig. 1). Compounds 1—5 were identified as bilagrewin (2), dihydrodehydrodiconiferyl alcohol (3), (−)-syringaresinol (4), and (−)-secoisolariciresinol (5), respectively, by comparison of their physical and spectroscopic data with literature values.

Compound 1 was obtained as a pale yellow solid, [α]D +2.4 in CHCl₃, with a molecular formula of C₂₀H₂₂O₈, which was assigned on the basis of the high-resolution (HR)-electrospray ionization (ESI)-time of flight (TOF)-MS (m/z 389.1224 [M+H]+, Caled 389.1236) and ¹³C-NMR (20 carbon signals) data. The IR spectrum of 1 suggested the presence of hydroxy (3393 cm⁻¹) groups and a conjugated carbonyl group (1663 cm⁻¹). The ¹H-NMR spectrum showed signals for four aromatic protons at δ 7.39 (d, J=1.8 Hz, H-6), 7.20 (d, J=1.8 Hz, H-6), 7.04 (d, J=1.8 Hz, H-2), and 7.01 (d, J=1.8 Hz, H-2'), two methoxy groups at δ 3.87 (s) and 3.79 (s), trans-olefinic protons at δ 7.52 (d, J=15.8 Hz, H-7') and 6.94 (dd, J=15.8, 4.0 Hz, H-8'), and an aldehyde group at δ 9.82 (d, J=4.0 Hz, H-9'). These ¹H-NMR spectral data, together with analyses of the ¹H-¹H shift correlation spectroscopy (COSY) and ¹H-detected heteronuclear multiple-quantum coherence (HMQC) spectra of 1 revealed that it contained two 1,3,4,5-tetrasubstituted aromatic rings and an α,β-unsaturated propenal group as the partial structures of 1.

group at δ 3.79 (3H, s) displayed a correlation with the C-3 signal at δ 149.6. These spectroscopic data of 1 indicated that 1 was a neolignan whose planar structure was essentially analogous to that of 2 except for the lack of the methoxy group as observed at δH 3.92 (OCH₃-5) and δC 56.7 (OC₃H₅) in 2. The proton spin-coupling constant of 3J_H-7,H-8/ H11005 7.9 Hz, together with the nuclear Overhauser effect (NOE) correlations between H-7 (δ 5.47) and H-9 (δ 4.26, 3.99), and between H-8 (δ 4.43) and H-6 (δ 7.39) in the NOE correlation spectroscopy (NOESY) spectrum of 1, allowed the relative configuration of C-7 and C-8 to be assigned as trans-oriented. The Cotton effects observed in the circular dichroism (CD) spectrum of 1 [(MeOH, Δε): 224 (+4.66), 236 (−3.02), 292 (−0.35) nm] were completely opposite to those of 2,11) and the absolute configurations at C-7 and C-8 of 1 were determined to be 7R and 8R, respectively. Thus, this compound was represented by structure 1 and named (7R,8R)-5-O-demethylbilagrewin.

Compounds 1—5 were evaluated for their cytotoxic activities against HL-60 cells and A549 cells. Neolignans 1 and 2 were cytotoxic to HL-60 cells with IC₅₀ values of 1.5±0.02 and 4.3±0.13 μM, and to A549 cells with 13.6±0.32 and 19.9±1.27 μM, respectively. Etoposide, used as a positive control, had respective IC₅₀ values of 0.48±0.03 and 4.41±0.39 μM against HL-60 cells and A549 cells. Compound 4 has been reported to show apoptosis-induced cytotoxicity against HL-60 cells with an IC₅₀ value of 5.8±0.2 μM15); however, 4 as well as 3 and 5 did not show the cytotoxic activities against HL-60 cells or A549 cells at sample concentrations up to 23 μM in our experiments (Table 2). As is evident from the microscopic photographs in Fig. 2, HL-60 and A549 cell deaths caused by 1 and 2 were shown to be partially mediated through the induction of apoptosis; nuclear chromatin condensation and cell shrinkage were characteristic features of the apoptosis-induced cells. HL-60 cells were more sensitive to 1 and 2 than A549 cells. Therefore, further studies were performed on the HL-60 cells. When apoptosis occurs, a typical apoptotic DNA ladder pattern can be observed in the agarose gel electrophoresis analysis of DNA. As shown in Fig. 3A, typical ladders of DNA fragmentation
were detected when HL-60 cells were treated with 10 μg/ml of 1 and 2 for 18 h. Compounds 1 and 2 were tested for their increasing activity of caspase-3, the common effector of most apoptotic pathways. Caspase-3 was markedly activated when HL-60 cells were treated with 1 and 2 at a sample concentration of 10 μg/ml for 6 and 15 h, respectively (Fig. 3B). Our findings demonstrate that neolignans 1 and 2 significantly induced apoptotic death in HL-60 cells and A549 cells. Compounds 1 and 2 were treated with NaBH₄ and CeCl₃ to give the corresponding C-9′ allyl alcohol derivatives (1a, 2a) (Fig. 1). Compounds 1a and 2a exhibited no apparent cytotoxic activities at a sample concentration of 23 μM against both tumor cell lines, suggesting that the aldehydes 1 and 2 is a structural requirement for the appearance of cytotoxicity in this type of lignans.

**Experimental**

Optical rotations were obtained using a DIP-360 (Jasco, Tokyo, Japan) automatic digital polarimeter. IR spectra were recorded with a JASCO FT-IR 620 spectrophotometer. NMR spectra (500 MHz for 1H-NMR) were recorded with a DRX-500 spectrometer (Bruker, Karlsruhe, Germany), using standard Bruker pulse programs. Chemical shifts are given as δ values with reference to tetramethylsilane (TMS) as an internal standard. HR-ESI-TOF-MS data were obtained with an LCT mass spectrometer (Waters-Micromass, Manchester, U.K.). Diaion HP-20 (Mitsubishi-Chemical, Tokyo, Japan), BW-300 silica gel (Fuji-Silysia Chemical, Aichi, Japan), and ODS silica gel (Nacalai Tesque, Kyoto, Japan) were used for CC. TLC was carried out on precoated Silica gel 60 F254 (0.25 mm thick, Merck, Darmstadt, Germany) and RP18 F254 plates (0.25 mm thick, Merck), and the spots were visualized by spraying the plates with 10% H₂SO₄ and then heating. HPLC was performed with a system composed of a CCPM pump (Tosoh, Tokyo, Japan), a CCP PX-8010 controller (Tosoh), RI-8010 (Tosoh) and Shodex OR-2 (Showa-Denko, Tokyo, Japan) detectors, and a Rhodyne injection port. A TSK gel ODS-100Z column (10 mm i.d. × 250 mm, 5 μm, Tosoh) was employed for preparative HPLC. The following materials and reagents were used for the cell cultures and the assay of cytotoxic activities: Spectra Classic microplate reader (Tecan, Salzburg, Austria); 96-well flat-bottom plate (Iwaki Glass, Chiba, Japan); JCRB 0085 HL-60 cells and JCRB 0076 A549 cells (Human Science Research Resources Bank, Osaka, Japan); fetal bovine serum (FBS) (Bio-Whittaker, Walkersville, MD, U.S.A.); 0.25% Trypsin-ethylenediamine tetraacetic acid (EDTA) solution, RPMI 1640 medium, minimum essential medium (MEM), etoposide, and 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-2H-tetrazolium bromide (MTT) (Sigma, St. Louis, MO, U.S.A.); penicillin G and streptomycin sulfate (Gibco, Grand Island, NY, U.S.A.). All other chemicals used were of biochemical reagent grade.

**Plant Material**

The heartwood of *S. album* was obtained from Uchida Wakannakuya, Tokyo, Japan. A small amount of the sample is preserved in our laboratory (06-004-SA).

**Extraction and Isolation**

The heartwood of *S. album* (1.0 kg of dry weight) was extracted with hot MeOH (12 l). After removing the solvent, the MeOH extract (91 g) was passed through a Diaion HP-20 column and successively eluted with 30% MeOH, 50% MeOH, MeOH, EtOH and EtOAc (each 91 l). CC of the MeOH-eluted fraction (40.0 g) on silica gel eluted with a stepwise gradient mixture of hexane-EtOAc (7:1, 5:1, 2:1, 1:1) and finally with MeOH alone, provided 13 fractions (A–M). Fraction K was chromatographed on ODS silica gel eluted with MeCN–H₂O (1:2; 1:1) and MeOH·H₂O (2:1) to yield 1 (13.0 mg), 2 (7.7 mg), 3 (12.8 mg), and 5 (5.0 mg). Fraction J was separated by an ODS silica gel column eluted with MeCN–H₂O (1:2; 1:1) and MeOH·H₂O (1:1) to give 4 (12.3 mg).

(7R,8R)-5-O-demethylbilagrewin (1): Pale yellow solid, [α]D²³ +2.4 (c=0.8, MeOH). IR νmax (film) cm⁻¹: 3393 (OH), 2936 (CH), and 1663 (C=O). UV λmax (MeOH) nm (log ε): 225 (3.36), 275 (2.66), CD λmax (MeOH) nm (Δε): 224 (+4.66), 236 (−3.02), 292 (−0.35). 1H- and 13C-NMR, see Table 1. HR-ESI-TOF-MS m/z: 389.1224 [M+H]+ (Calcd for C₁₉H₁₉O₈, 389.1236).

**Reduction of 1 and 2**

NaBH₄ (1.0 mg) and CeCl₃·7H₂O (5.0 mg) were added to a solution of 1 (5.0 mg) in MeOH (0.5 ml), and then the mixture was stirred at room temperature for 6 h. After 0.1 M HCl (1.0 ml) was added, the reaction mixture was extracted with EtOAc (3 ml×3) and concentrated under reduced pressure. The crude product was purified by CC on silica gel using MeCN–H₂O (1:1) to give 4 (12.3 mg), 5 (12.8 mg), and 3 (7.7 mg) compounds. The same procedures, 2 (5.0 mg) was reduced to 2a (0.6 mg), of which the physicochemical physical and spectral data were identical to those of ntidin. ²⁷

**Compound 1a: Pale yellow solid, [α]D⁰₂⁵ −2.0 (c=0.2, MeOH). IR νmax (film) cm⁻¹: 3430 (OH), 1641 (C=O). UV λmax (MeOH) nm (log ε): 227 (3.84), 272 (3.44), CD λmax (MeOH) nm (Δε): 226 (+5.17), 230 (−8.41), 279 (−3.12). 1H- and 13C-NMR, see Table 1. HR-ESI-TOF-MS m/z: 413.1205 [M+Na]+ (Calcd for C₂₀H₂₁O₈, 413.1212).

**HL-60 Cell Culture Assay**

HL-60 cells were maintained in an RPMI 1640 medium containing 10% FBS supplemented with 1-t-glutamine, 100 units/ml of penicillin G, and 100 μg/ml of streptomycin sulfate. The leukemia cells were washed and re-suspended in this medium to 4×10⁶ cells/ml. HL-60 cells were incubated at 37 °C for 18 h with 10 μg/ml of 1, 2, or etoposide (E).

**Fig. 3.** (A) Induction of DNA Fragmentation by 1, 2, or Etoposide in HL-60 Cells

HL-60 cells were incubated at 37 °C for 18 h with 10 μg/ml of 1, 2, or etoposide (E). DNA was then extracted and applied to agarose gel electrophoresis. M: DNA marker, C: control.

(B) Caspase-3 Activity in 1, 2, or Etoposide-Treated HL-60 Cell Lysates

HL-60 cells were incubated at 37 °C for 6 and 15 h, respectively, with 10 μg/ml of 1, 2, or etoposide. Each value represents mean±S.E. from triplicate determinations. Caspase-3 activity was expressed as % of control. The absorbances at 405 nm of the cleaved product by either 6 or 15 h in the control were 0.11 and 0.25, respectively. ∗p<0.05, significantly different from the control group by the Student’s t test.

²⁶ Data are presented as the mean value±S.E.M. of three experiments performed in triplicate.
cells/ml, and 196 µl of this cell suspension was placed in each well of a 96-well flat-bottom plate. The cells were incubated in 5% CO2 air for 24 h at 37°C. After incubation, 4 µl of EtOH-H2O (1:1) solution containing test compounds were added to give final concentrations of 0.1—20 µg/ml. 4 µl of EtOH-H2O (1:1) was added into the control wells. The cells were further incubated for 72 h in the presence of each agent, and then the cell growth was evaluated by a modified MTT reduction assay. Briefly, after terminating the cell culture, 10 µl of 5% EtOH in MTT in PBS was added to every well, and the plate was reincubated in 5% CO2 air for 4 h at 37°C. The plate was then centrifuged at 1500 x g for 5 min to precipitate the cells and MTT formazan crystals. The plate was mixed on a microshaker for 10 min, and then read on a microplate reader at 550 nm.

**A549 Cell Culture Assay**

A549 cells were maintained in MEM containing 10% FBS in a humidified 5% CO2 atmosphere. Cells were trypsinized and re-suspended in this medium to 1 x 105 cells/ml, and 100 µl of this cell suspension was placed in each well of a 96-well flat-bottom plate. The cells were incubated in 5% CO2 air for 24 h at 37°C. After washing once with phosphate buffered saline (PBS), they were treated for 72 h in the presence of 196 µl of fresh medium with 4 µl of test compounds. Then the cell growth was evaluated by a modified MTT reduction assay. The plate was reincubated in 5% CO2 air for 4 h at 37°C with MTT 0.2 mg/ml in MEM supplemented with 10% FBS. After the medium was removed, the MTT formazan crystals were dissolved with 100 µl of DMSO. The plate was mixed on a microshaker for 10 min and then read on a microplate reader at 550 nm.

**Assay for Detection of DNA Fragmentation**

The cells were incubated at 37°C for 18 h. DNA was extracted with a commercially available kit (Wizard Genomic DNA Purification Kit, Promega, WI, U.S.A.). In brief, cells (1.2 x 105 cells) were centrifuged at 10000 g for 5 min at 10000 g. The cell plate was reincubated in 5% CO2 air for 4 h at 37°C with MTT 0.2 mg/ml in MEM containing 10% FBS in a humidified 5% CO2 atmosphere. Cells were centrifuged at 37°C for 18 h. DNA was extracted with a commercially available kit (Wizard Genomic DNA Purification Kit, Promega, WI, U.S.A.). In brief, cells (1.2 x 105 cells/ml, equivalent to 200 µl) were treated with 4 µl of DNA rehydration solution and incubated at 37°C for 15 min. Protein precipitation solution (200 µl) was added to the RNaseA-treated cell lysate, and the mixture was incubated for 5 min on ice and centrifuged at 10000 g for 5 min. The supernatant was transferred to a clean 1.5 ml microcentrifuged tube containing 600 µl of 2-propanol and mixed by inversion. After centrifugation at 10000 g for 5 min, DNA was visible as a small white pellet, and it was washed with 70% EtOH. Finally, the pellet was resuspended in 25 µl of DNA rehydration solution and incubated at 65°C for 1 h, which was stored at −20°C until use. The sample (10—15 µl) was applied to 2% agarose gel electrophoresis in a 40 mM Tris-acetate buffer (pH 7.4) at 50 V for 1 h. DNA molecular weight marker (pH marker, Takara, Shiga, Japan) and DNA from apoptotic HL-60 cells induced by 10 µg/ml etoposide were used for calibration. The DNA fragmentation pattern was examined in photographs taken under UV illumination.

**Assay for Caspase-3 Activation**

The activity of caspase-3 was measured using a commercially available kit (APPOCYTO Caspase-3 Colorimetric Assay Kit, MBL, Aichi, Japan). HL-60 cells (2 x 105) were treated with test samples for 6 and 15 h, respectively, and the cells were centrifuged and collected. Cell pellets were suspended in 60 µl of ice cold cell lysis buffer and incubated on ice for 10 min. This cell pellet suspension was centrifuged at 10000 g for 5 min, and the supernatant was collected. The cell lysate (50 µl, equivalent to 200 µg of protein) was mixed with 50 µl of 2× reaction buffer containing the substrates for caspase-3 (DEVD-pNA (p-nitroanilide)). After incubation for 2 h at 37°C, the absorbance at 405 nm of the liberated chromophore pNA was measured using a microplate reader. The activity of caspase-3 was evaluated in triplicate.
