China; and Department of Pharmacology, Institute of Materia Medica, Chinese Academy of Medical Sciences; Beijing 100050, P.R. China.

Bioassay-guided fractionation of an $n$-BuOH extract of the lateral roots of Aconitum carmichaeli led to the isolation of 5 cardioactive $\text{C}_{19}$-diterpenoid alkaloids: N-deethylaconine (1), beiwutinine (2), hypaconine (3), mesaconine (4), and 15$\alpha$-hydroxyneoline (5). N-Deethylaconine and beiwutinine are new aconitine-type $\text{C}_{19}$-diterpenoid alkaloids. Hypaconine was isolated from this species for the first time. Among them, mesaconine, hypaconine, and beiwutinine showed the strongest cardiac actions on the isolated perfused bullfrog heart. Furthermore, mesaconine has protective effects, including improved inotropic effect and left ventricular diastolic function, on myocardial ischemia-reperfusion injury in rat at a dose of $10^{-9}$ mol/L. However, mesaconine has almost no effect on heart rate.

Key words Aconitum carmichaeli; cardioactive constituent; Fu Zi; N-deethylaconine; beiwutinine

Fu Zi, a distinguished traditional Chinese medicine, is the lateral roots of Aconitum carmichaeli (Ranunculaceae). The species, originally growing in the district of Jiangyou in Sichuan province of China, has been clinically used for more than two thousand years. Aconitum carmichaeli has now been widely grown in Hanzhong of Shaanxi Province, LiJiang of Yunnan Province, etc. in addition to the district of Jiangyou. Furthermore, other Eastern Asian countries, such as Japan and Korea, also grow Aconitum carmichaeli for the clinical use as traditional medicine. Fu Zi, as an critical emergency drug in traditional Chinese medicines, is used to treat heart failure. The mother roots of the same plant (A. carmichaeli), designated as “Chuan Wu,” is also used in traditional Chinese medicine for the clinical treatment of pains and rheumatics.

For several decades, researchers paid more attention to the cardioactive components of the lateral roots of A. carmichaeli. Chinese and Japanese scholars have independently verified that Fu Zi has indeed cardiac effects. In 1976, Japanese scholar Kosuge et al. isolated a trace amount of cardioactive component, dl-demethylcoclaurine, from the roots of Japanese A. japonicum Thum, which are of interest to a lot of scientists. Three years later, another Japanese scholar Konno and his co-workers isolated a water-soluble component coryneine chloride, which can improve blood pressure, from Japanese “Bushi” (A. carmichaeli). Afterwards, Chen and Liang obtained a weak cardioactive component, salsonine, from Fu Zi. During the period of 1975—1980, extensive investigation of the synthesis and clinical study of dl-demethylcoclaurine were carried out by Chinese scientists. It was concluded that dl-demethylcoclaurine was suitable to the clinical treatment for chronic arrhythmia and low cardiac output syndrome, and could be used as a diagnostic agent for coronary heart disease. During the 10 years after this, there was almost no report on the investigation of the cardioactive components of Fu Zi until Han et al. and Xu et al. isolated the cardioactive components, uracil and fuzinoside, from Fu Zi, respectively. In addition to the above-mentioned cardioactive compounds, numerous of the components including the diterpenoid alkaloids have also been isolated from the lateral roots of Aconitum carmichaeli. However, no cardiac effect of these compounds has been reported. In this paper, we used an isolated bullfrog heart testing to guide the fractionation of water-soluble constituents of the lateral roots of Aconitum carmichaeli, leading to the isolation of five cardioactive $\text{C}_{19}$-diterpenoid alkaloids: N-deethylaconine (1), beiwutinine (2), hypaconine (3), mesaconine (4), and 15$\alpha$-hydroxyneoline (5).

Results and Discussion

The fractions A, B, C were obtained from the lateral roots of Aconitum carmichaeli (22 kg) by sequential reflux with hot water, precipitation with 75% ethanol, and extraction with diethyl ether and n-butanol after basifying. Among them, only n-butanol extract (fraction B) exhibited significant cardiac actions on the isolated bullfrog hearts. Consequently, fraction B was subjected to repeated column chromatography over silica gel H (CHCl$_3$–MeOH), leading to the isolation of N-deethylaconine (1), beiwutinine (2), hypaconine (3), mesaconine (4), and 15$\alpha$-hydroxyneoline (5).

N-Deethylaconine (1): white amorphous powders, $[\alpha]_D^{20} +25.4$ ($c=0.61$, MeOH). Its molecular formula was determined as C$_{23}$H$_{37}$NO$_9$ by the $^{13}$C-NMR spectrum and high resolution-electrospray ionization-mass spectra (HR-ESI-MS) data (Found: m/z 472.2549 [M + H]$^+$, Caled: m/z 472.2547 [M + H]$^+$). The IR spectrum showed an absorbance band at 3357 cm$^{-1}$ for hydroxyl groups. The $^1$H-NMR spectrum showed the presence of four methoxyl groups ($\delta$ 3.34, 3.39, 3.43, 3.64, each 3H, s) and the presence of five hydroxyl groups in addition to four methoxyl groups. The

above-mentioned evidence, in combination with the biogenetic consideration, suggested this compound to be a C19-diterpenoid alkaloid.47) On the other hand, a doublet signal at $\delta^H 3.89$ ($J=4.1$ Hz) was attributed to H-14$\beta$.47) A one-proton doublet signal at $\delta^H 4.18$ ($J=3.9$ Hz) was assigned to H-3$\beta$ based on the correlations between this signal and C-1 ($\delta^C 79.9$) as well as C-18 ($\delta^C 76.8$) in the heteronuclear multiple bond connectivity (HMBC) spectrum. The assignment of H-15 ($\delta^H 4.51$, d, $J=6.0$ Hz) was based on the correlations of H-15 and C-8 ($\delta^C 77.9$ s) and C-16 ($\delta^C 91.6$ d) in the HMBC spectrum. Four methoxyl groups were located to C-1, C-6, C-16, and C-18, respectively, based on the correlations between $\delta^H 3.39$ C-1 ($\delta^C 77.9$), $\delta^H 3.43$ C-6 ($\delta^C 81.7$), $\delta^H 3.64$ C-16 ($\delta^C 91.6$), and $\delta^H 3.34$ C-18 ($\delta^C 76.8$) in the HMBC spectrum (Fig. 1). The $\alpha$-orientation of H-3 was established according to the correlation between H-3 ($\delta^H 4.18$) and H$_2$-18 ($\delta^H 3.51$, 3.59) in its nuclear Overhauser effect spectroscopy (NOESY) spectrum (Fig. 1). Its Dreiding molecular modeling shows that the dihedral angles between H-16$\alpha$ and H-15$\beta$, and between H-16$\alpha$ and H-15$\alpha$ are around 45° and 75°, respectively (ring D possesses boat conformation).47) Theoretically, $J_{16\alpha-15\beta}$ and $J_{16\alpha-15\alpha}$ should be ca. 8 Hz and ca. 3 Hz. The observed value is 6.0 Hz, suggesting the $\alpha$-orientation of 15-OH. All signals in the $^1H$ ($^13C$) spectra of this compound (Table 1) were assigned based on its 2D-NMR spectra. Thus, the structure of $N$-deethylaconine was established as 1.

Beiwutinine (2): White amorphous powers, $[\alpha]_D^{20} +22.0$ (c=0.51, MeOH). Its molecular formula was established as C$_{24}$H$_{39}$NO$_{10}$ based on its $^13$C-NMR spectrum and HR-MS data (Found m/z 502.2656 [M+H]$^+$, Calcd C$_{24}$H$_{40}$NO$_{10}$, 502.2652). Its structure was initially suggested to be 2 based on the comparison of its TLC behavior and electrospray ionization-mass spectra (ESI-MS) data with those of the authentic sample,48,49) and was finally confirmed by the 2D-NMR spectra. All of the signals (Table 1) in its $^1H$ ($^13C$-) NMR spectra were assigned by the correlations in the 2D-NMR spectra.

Bioassay results exhibited that 4 C$_{19}$-diterpenoid alkaloids (1—4) have cardioactive effect on the isolated bullfrog hearts,50) while 15$\alpha$-ishydroxyneoline (5) only showed very short cardiac action (Table 2). Of them, hyapaconine, mes-
aconine, and beiwutinine have optimal cardiac actions. To observe the effects of these alkaloids on heart failure, hypaconine and mesaconine were selected for further study on myocardial ischemia-reperfusion injury in isolated rat hearts. In this study, the cardiac parameters of maximal rise rate of coronary flow, left ventricular pressure, left ventricular end-diastolic pressure, and heart rate were observed. It can be concluded from the observed results: 1) hypaconine and mesaconine has almost no effect on coronary flow and heart rate; 2) mesaconine exhibited significant effects on left ventricular pressure in 10—40 min relative to the control group (Table 3); 3) mesaconine showed significant effects on left ventricular end-diastolic pressure in 20—60 min relative to the control group, while hypaconine did not show significant effects (Table 4). The above-mentioned evidence indicated that mesaconine has protective effects, including improved inotropic

**Effect and left ventricular diastolic function, on myocardial ischemia-reperfusion injury in rat at a dose of 10−3 mol/L.**

**Conclusion**

It is known that numerous of diterpenoid alkaloids have already been isolated from the lateral roots of *Aconitum carmichaeli*. However, none of them showed cardiac effects. In this paper, we firstly reported 5 cardioactive C19-diterpenoid alkaloids. Among them, N-deethylaconine and beiwutinine are new diterpenoid alkaloids; while hypaconine was isolated for the first time from this species. All these compounds are soluble in water. N-Deethylaconine is not stable under acidic conditions.

Bioassay results exhibited that 5 C19-diterpenoid alkaloids (1—5) have cardioactive effect on the isolated bullfrog hearts and that hypaconine, mesaconine, and beiwutinine have optimal cardiac actions. 15α-Hydroxyaconine has a significant short duration of action relative to other alkaloids. We also observed that mesaconine has protective effects, including improved inotropic effect and left ventricular diastolic function, on myocardial ischemia-reperfusion injury in rat at a dose of 10−3 mol/L. This result is inconsistent with the results reported by Hirohisa,50 in which mesaconine was reported to have no cardiac effect on both frog and toad hearts. This inconsistency might be caused by the different animal models and concentrations of the samples. In literature31 the test concentration of mesaconine is 1 mg/mL, while a concentration of 5 mg/mL was employed in our testing.

In conclusion, the results from this study might be helpful to elucidate the mechanism of action of the cardiac effect of Fu Zi, and we have indeed found a lead compound with cardiac effect.

Further structure–activity relationship study on the cardiac effect of mesaconine and its derivatives is in progress, which will be reported in due course.

**Experimental**

**General Experimental Procedures** Melting points were determined on a Kofler block (uncorrected). Optical rotations were measured in a 1.0-dm cell on a Perkin-Elmer 341 polarimeter at 20±1°C. IR spectra were obtained on a Nicolet FT-IR 200 SXV spectrophotometer. 1H- and 13C-NMR spectra were taken on a Varian Unity INOVA 400/54 NMR spectrometer in CDCl3 with TMS as the internal standard. The ESI-MS and HR-ESI-MS were recorded on a VG Auto Spec 3000 or a Finnigan-MAT 90 instrument. Silica gel H (Qingdao Marine Chemical Factory, Qingdao, China) was used for column chromatography. Development system: Si (CHCl3–MeOH–conc. NH4OH = 85 : 14 : 1), S2 (EtOAc–MeOH–conc. NH4OH = 83 : 16 : 1), Si (hexane–EtOAc–EtOH = 1 : 3 : 1). TLC developing chambers were saturated with conc. NH4OH. Zones on TLC (silica gel G) plates were detected with the modified Dragendorff’s reagent.

**Plant Material** The lateral roots of *Aconitum carmichaeli* were collected in the district of Jiangyou, Sichuan province, China, in June 2004. The plant was identified by Professor Wang Tian-Zi, West China College of Pharmacy, Sichuan University, and a voucher specimen (No. 04601) has been deposited in the West China College of Pharmacy at Sichuan University.

**Extraction and Isolation** The powdered lateral roots of *Aconitum carmichaeli* (22 kg) were macerated with water (88 L) overnight, and then refluxed for 1 h. After filtration, the powders were refluxed twice with water (66 L each time) for 1 h. The combined filtrates were concentrated to about 20 L, to which was added 95% ethanol (75 L) to adjust the mixture in 75% ethanol. After standing at room temperature overnight, the insoluble material was removed by filtration and the solvents were evaporated to furnish a residue (175 g). The residue was dissolved in water (1000 mL) and basified with concentrated ammonium hydroxide to pH 10. The subsequent mixture was extracted with diethyl ether (1000 mL × 3, fraction A, 15 g), the aqueous layer was extracted with n-butanol (saturated with water, 1000 mL × 3). The combined n-butanol extracts were concentrated to give fraction B (92 g), and the aqueous fraction was concentrated to give fraction C (70 g). Fraction B (80 g) was subjected to column chromatography (CC) (silica gel H, 400 g; CHCl3–MeOH = 95:5→85:15) to
give the fractions 1—6. Frs. 4—5 were applied repeatedly to CC (silica gel H, 260, 50, 15 g, respectively) eluting with CHCl3—MeOH = 90:10 → 80:20) to furnish N-deethylnaconine (1, 60 mg), beiwutinine (2, 56 mg), hypaconine (3, 125 mg), mesaconine (4, 105 mg), and 15α-hydroxynorleoline (5, 150 mg). The known alkaloids 3—5 were identified based on the comparison of TLC behavior (S, S) and $^1$H- ($^13$C)-NMR spectra with those of authentic samples, which were provided by our laboratory.

### Physical and Spectroscopic Data of the Compounds

**N-Deethylnaconine (1):** white amorphous powder, $R_f$ 0.40 (S), $[\alpha]_D^{20}$ +25.4 ($c$ = 0.61, MeOH). IR (KBr) $\nu$ max 3357 cm$^{-1}$, $^1$H-NMR (400 MHz, CD$_3$OD) and $^{13}$C-NMR (100 MHz, CD$_3$OD), see Table 1. ESI-MS $m/z$ 472 [M+H]$^+$. HR-ESI-MS $m/z$ 472.2549 [M+H]$^+$. [Cacl for C$_2$H$_{15}$NO$_5$ 472.2547].

**Beiwutinine (2):** White amorphous powder, $R_f$ 0.30 (S), 0.21 (S), 0.22 (S), $[\alpha]_D^{20}$ +22.0 ($c$ = 0.5, MeOH). IR (KBr) $\nu$ max 3380, 2937, 2825, 1645, 1454, 1097 cm$^{-1}$, $^1$H-NMR (400 MHz, CDCl$_3$) and $^{13}$C-NMR (100 MHz, CDCl$_3$), see Table 1. ESI-MS $m/z$ 502 [M+H]$^+$. HR-ESI-MS $m/z$ 502.2656 [M+H]$^+$. [Cacl for C$_2$H$_{15}$NO$_5$ $^1$H]$^+$. 502.2652].

### Animal Experimental

**Experimental Animals:** Sprague-Dawley (SD) male rats used in the experiments were purchased from the laboratory animal center at the Chinese people's liberation army military academy of medical sciences with Qualified number: SCXK 2007-0004.

**Samples:** Compounds 1—5 and the extracts (A—C) were dissolved in Ringer's solution to make the test concentrations; hypaconine (molecular w8: 485, soluble in water) was dissolved in Krebs–Henseleit (KH) to prepare the test concentrations; mesaconine (molecular w8: 469, soluble in water) was dissolved in KH to make the test concentrations.

**Positive Control:** Deslanoside Injection, manufactured by Shanghai Xudong Haipu Pharmaceutical Co., Ltd. with batch number: 090409, was dissolved in KH to corresponding concentration.

**Krebs–Henseleit (KH) Buffer:** Contained (g/2L) NaCl 13.7918, KCl 0.7008, CaCl$_2$ 0.56605, MgSO$_4$ 0.2841, KH$_2$PO$_4$ 0.3212, NaHCO$_3$ 4.1803, glucose: 4.3994.

**Experimental Apparatus:** Langendorff heart perfusion device (BIOPAC in U.S.A.), DC100A more physical recorder (BIOPAC in U.S.A.).

**Experimental Methods:** The experiment was carried out according to the procedure described in the literature. Specifically, rats were anesthetized by injecting 50 mg/kg sodium pentobarbital intraperitoneally. Hearts were isolated and kept filled latex balloon was filled based on the concentrations specified in the experimental design. After the stabilization, hearts were perfused for 10 min and then normothermic no-flow global ischemia for 20 min, followed by reperfusion for 60 min. The coronary effluent was measured with volumetric cylinder. Each heart was perfused in the presence or absence of hypaconine (10$^{-4}$ mol/L), mesaconine (10$^{-4}$ mol/L) or deslanoside (10$^{-5}$ mol/L). Hypaconine, mesaconine or deslanoside was treated 10 min before the introduction of ischemia and continued to the end of the reperfusion.

**LVEDP:** the peak positive (dP/dt max) and HR were recorded from 10 min before the introduction of ischemia to the end of reperfusion. A polygraph recorder (DC100A, BIOPAC, U.S.A.) and Acq373 software were used for recording and analysis. t-Test was applied to calculate the mean value and the standard error.
