and recrystallization of the eluate from benzene gave II*d (10 mg) as colorless needles. mp 171—173*. [α]D +56° (c=0.11). Anal. Caled. for C19H16O3Cl-C6H4: C, 72.71; H, 7.08. Found: C, 72.82; H, 6.93. IR νmax cm⁻¹: 1758 (C=O). NMR (1.6%, solution in CDCl₃) δ: 0.95 (3H, s, 18-CH₃), 3.82 (3H, s, 9- OCH₃), 4.38 (1H, t, J=3.9 Hz, 16ß-H), 5.31 (1H, s, 3-οH), 6.49 (1H, s, 4-H), 6.78 (1H, s, 1-H).

2-Hydroxy-3-methoxy-16β-chloroestra-1,3,5(10)-trien-17-one (III) — II*c (50 mg) was dissolved in benzene, adsorbed on Al₂O₃ (100 mg), and allowed to stand overnight. Elution with benzene gave a mixture of two C₁₈ epimers as colorless oil. A solution of this crude product was shaken with 10% Pd/C (40 mg) under a stream of H₂ gas for 2 hr. After usual work-up the crude product obtained was submitted to preparative TLC by multiple runs using hexane-CHCl₃ (1:1) as developing solvent. Elution of the adsorbent corresponding to the spot with AcOEt and recrystallization of the eluate from MeOH gave III*d (20 mg) as colorless needles. mp 175—177°. [α]D +120° (c=0.10). Anal. Caled. for C₁₉H₁₈O₃Cl-1/2H₂O: C, 66.37; H, 7.04. Found: C, 66.21, 66.12; H, 6.86, 6.91. IR νmax cm⁻¹: 1753 (C=O). NMR (5% solution in CCl₄) δ: 1.02 (3H, s, 18-CH₃), 3.80 (3H, s, 9-OCH₃), 5.17 (1H, s, 2-ΟH), 6.39 (1H, s, 4-H), 6.66 (1H, s, 1-H).

Studies on Berberine Derivatives and Related Alkaloids. VII.¹ On the Biosynthesis of Protopine²

CHIKI TANI and KIYOSHI TAGAHARA

Kobe Women's College of Pharmacy³

(Received March 14, 1974)

Contrary to our expectations, tetrahydrocoptisine methochloride (III A) was not incorporated into corynoline.⁴ We further examined the fate of III A and found that this alkaloid was actually incorporated into protopine (I) on which we describe in this paper.

Incorporation of (+)-reticuline, (−)-scoulerine, stylopine and cheilanthifoline besides S-methyl group of L-methionine into protopine (I) have already been reported.⁵ However, there was no evidence of the incorporation of tetrahydrocoptisine N-methyl derivative (III) into protopine (I).

(N¹⁴CH₃)-tetrahydrocoptisine methochloride (III A) was administered to Corydalis incisa in May by the cotton wick method and radioactive protopine (I) was obtained through the usual work up, 0.19% incorporation.

In order to prove the labelled position of protopine (I), the alkaloid was reduced with LiAlH₄ to give dihydroprotopine (II), which was heated with 20% HCl yielding tetrahydrocoptisine methochloride (III A).

⁴) This work was presented at the 91th Annual Meeting of the Pharmaceutical Society of Japan, Fukuoka, April, 1971, Abstracts of Papers, p. 277.
The iodide (III B) derived from III A was decomposed by heating at 270° under nitrogen atmosphere and the resulting methyl iodide was converted into (CH₃)₄NI which was found to be radioactive. Purification of the reaction mixture also gave non-radioactive tetrahydrocoptisine (IV).

Thus it was substantiated that tetrahydrocoptisine N-methyl derivative (III) served as a precursor of protopine (I) maintaining its N-methyl group at the original position.

Experimental

Administration of (N-³¹CH₃)-Tetrahydrocoptisine Methochloride (III A) to Corydalis incisa and Isolation of Protopine (I)—Tetrahydrocoptisine methochloride (III A) (15 mg) was dissolved in water (10 ml) and administered by the cotton wick method to ten Corydalis incisa plants at their flowering stage in May. Seven days after the beginning of the administration, the plants (dry weight 64 g) were cut into pieces and extracted with MeOH (500 ml). The solvent was removed in vacuo and the residue was extracted with 2% tartaric acid (2 x 100 ml). After washing with ether (100 ml), the extracts were made alkaline with aq. ammonia and extracted with CHCl₃ (3 x 80 ml). The CHCl₃ extracts were combined and dried over anhyd. Na₂SO₄. After removal of the solvent, the resulting crude tertiary bases were diluted with carrier protopine (8 mg) and chromatographed on a column of silica gel with benzene: ether (1:1) and then with CHCl₃: MeOH (9:1) as eluents.

The crystals obtained from CHCl₃: MeOH fractions were colored violet with conc. H₂SO₄ and were identified with an authentic sample of protopine (I) by TLC (silica gel, CHCl₃: MeOH, 9:1). The radioactive protopine was diluted with carrier (67.6 mg) and repeatedly recrystallized from CHCl₃: MeOH to give colorless needles having a constant specific activity, 57 mg, mp 207°, spec. activity 2.55 x 10⁶ dpm/mmol.

Degradation of Protopine (I), Formation of Dihydroprotopine (II)—To a solution of radioactive protopine (54.2 mg) in absolute benzene was added LiAlH₄ (134.9 mg) dissolved in absolute ether and the mixture was stirred under reflux for 3 hr. After addition of 20% H₂SO₄ to the reaction mixture cooled in an ice-bath, the acidic solution was made alkaline with 30% NaOH and extracted with benzene. After drying over K₂CO₃, the solvent was removed in vacuo to give a brown viscous residue (37.5 mg). Recrystallization of the residue from MeOH gave colorless needles, mp 152—153°, which were identified with an authentic

6) Unless otherwise noted, Silica gel G acc. to Stahl (E. Merck) was used for the thin-layer chromatography (TLC) and silica gel plates PF₂₅₄ (E. Merck) were employed for the radio TLC. The spots were detected by exposing the plates to iodine vapour. Silica gel (Mallinckrodt) were used for column chromatography. The solvent ratio was expressed by volume. The radioactivity was measured by a Ten Liquid Scintillation Counter Model GSL-260 with samples dissolved in a scintillation mixture consisting of dioxane (10 ml), naphthalene (1 g), 2,5-diphenyloxazole (40 mg), 2,2’-diphenylene-bis-(5-phenyl-oxazole) (0.6 mg).
sample of dihydroprotine (II) by admixture and TLC (silica gel, CHCl₃: MeOH, 4:1). spec. activity 2.48 × 10⁶ dpm/mmol.

Tetrahydrocoptisine Methiodide (III B)—Dihydroprotine (II) (37 mg) was dissolved in 20% HCl (5 ml) and refluxed over a free flame for 10 min. After addition of potassium iodide to the reaction mixture, the resulting precipitates were collected by centrifugation. Recrystallization of the precipitates (67 mg) from MeOH gave colorless needles, mp 260° (decomp.), spec. activity 2.37 × 10⁶ dpm/mmol.

Pyrolysis of Tetrahydrocoptisine Methiodide (III B)—The iodide (III B) (60 mg) was heated on an oil bath at 270—280° in a stream of N₂ for 1 hr and the resulting methyl iodide was introduced into a solution of 30% trimethylamine. After removal of the solvent, the resulting white residue (12.5 mg) was recrystallized from MeOH, which was identified with an authentic sample of tetramethylammonium iodide by TLC (silica gel, CHCl₃: MeOH, 4:1), spec. activity 2.44 × 10⁶ dpm/mmol.

The residue in the reaction flask was chromatographed on silica gel with benzene:ether (1:1) as eluent to give a non-radioactive light yellow residue (3.1 mg), which was identified with an authentic sample of tetrahydrocoptisine (IV) by TLC (silica gel, benzene: ether, 1:1).

**Effect of Gastric Emptying on Absorption of Aminopyrine in Rat**

OSAMI TSUZUKI, ATSUKO NODA, and SADAO IGUCHI

Faculty of Pharmaceutical Sciences, Kyushu University

(Received March 15, 1974)

In the previous paper, it was described that the initial plasma concentration of aminopyrine increased significantly by the simultaneous oral administration with barbital in rabbits as compared to the single administration. Furthermore, it was also reported that the rate of gastric emptying of aminopyrine increased by barbital in spite of the inhibition of the gastric emptying by aminopyrine. As for gastrointestinal absorption of aminopyrine, it has been known that the delay of the time at which the peak level of plasma concentration of aminopyrine becomes the highest is proportional to the increasing dose. It is not clear, however, why such a delay of it occurs. In consideration of the reason of the delay, the gastric emptying might be one of the important factors.

The present study was performed to clarify the relationship between the gastric emptying and the absorption rate of aminopyrine in rat.

**Experimental**

Procedure—Male Donryu rats weighing between 190—210 g were fasted for 14—16 hr. However, drinking water was permitted ad libitum until 2 hr before the experiment. One ml of 0.07% phenol red solution containing aminopyrine (20 mg/kg or 50 mg/kg) was introduced into the stomach by intubation.
