A new debenzylation method using aluminum chloride in benzene or anisole, which had been developed by us for N-benzyl-2-acyl- and -2-ethoxycarbonylindoles, was applied to benzyl derivatives of other types of indoles and related compounds. Among them, N-benzyl derivatives of fully aromatized indoles, carbazoles and β-carbolines, and some benzamides were debenzylated successfully, whereas those of oxindoles and heterocyclic amidines were not. As to the effect of a p-substituent on the benzyl group, it was found that an electron-donating substituent accelerates deprotection, whereas an electron-attracting substituent delays or prevents deprotection.

Keywords debenzylation; aluminum chloride; indole; benzamide; benzene; anisole

Some years ago we reported2) a novel method for the debenzylation of protected nitrogen of indoles using aluminum chloride in benzene or anisole. In this reaction N-benzylindoles (1a, b) were easily converted to the corresponding NH-indoles (2a, b) under mild conditions, and the benzyl cation thus formed was trapped with benzene or anisole to form diarylmethane derivatives (3). The mechanism proposed in the case of ethyl 1-benzyl-1H-indole-2-carboxylate is shown in Chart 1, and is reminiscent of the Fries rearrangement. However, this method was applied only to the N-benzyl derivatives of ethyl indole-2-carboxylates (2a) and 2-acylindoles (2b). In this paper we describe the application of this method to other types of indoles and related compounds to examine its scope and limitations. If the expected debenzylation proceeds, the method is expected to be practically useful, because it has been reported that removal of the N-benzyl group from an amide by catalytic hydrogenolysis is rather difficult.3)

The required unknown N-benzyl derivatives (5) were prepared by benzylation of the corresponding NH compounds (4) or by other methods, as shown in Table I, and their characteristics are listed in Table II.

Debenzylation reaction was carried out under the conditions used for the previous experiment2); that is, N-benzyl compounds (5) (1 eq) were allowed to react with aluminum chloride (4—6 eq) in benzene, or anisole at 0—50 °C. The results are summarized in Table III, and represent the highest yield obtained for each benzyl compound after many trials. The products, NH-compounds (4), were identical with authentic samples in terms of infrared (IR) and 1H-nuclear magnetic resonance (1H-NMR) spectra, and melting points. The compounds which did not undergo debenzylation are given below Table III.

Run 1 shows that a 3-acyl group in the ethyl indole-2-carboxylate skeleton does not prevent debenzylation. However, the reaction was accompanied with formation of 3-acyt1-1H-indole-2-carboxylic acid (9) (9%) by hydrolysis, and some starting material (5a) was recovered (8%). Run 2 shows that the 2-amide group in place of the 2-ethoxycarbonyl group was also effective for debenzylation, although anisole gave a better result than benzene as a solvent. Successful debenzylation of the 3-acyl-2-unsubstituted indoles (5e) (run 3) shows that the presence of a 2-acyl group is not essential for debenzylation.

It is noteworthy that N-benzyl derivatives of fully aromatized indoles, carbazoles and β-carboline (5d and 5e in runs 4 and 5) were debenzylated easily in almost the same manner as 2-alkoxycarbonyl- and 2-acylindoles2) (1a, b). On the basis of this knowledge, this method was successfully applied to the synthesis of creatine,4) a new kind of

\(\beta\)-carboline alkaloid, and would also be applicable to our synthesis\(^5\) of ellipticine, in which the debenzylated step was carried out by means of the troublesome Birch reduction. In the present debenzylation the product was sometimes contaminated with a small amount of "C\(_6\) benzyl-NH compounds," which would be formed by the attack of benzyl cation at the carbon moiety of the debenzylated \(\text{N}\)-product. This was observed by mass spectrometry (MS, same molecular weight as starting material), \(^1\)H-NMR spectroscopy (the presence of an isolated \(-\text{CH}_2\)- and an \(\text{NH}\) group), and IR spectroscopy (the presence of an \(\text{NH}\) group) in the case of \(\text{5g}\).

\(\text{N}\)-Benzyl-1,2,3,4-tetrahydrocarbazole (\(\text{5f}\), run 6) seemed to undergo debenzylation but gave a mixture of many products, when checked by thin layer chromatography (TLC), probably because \(\text{5f}\) and the expected product (\(\text{NH}\)-compound), which has similar reactivity to usual indoles (indoles which are not stabilized by an electron-negative substituent), are susceptible to acid (aluminum chloride) to give a mixture of products. Ethyl 1-benzyl-1\(\text{H}\)-pyrrole-2-carboxylate (\(\text{5g}\), run 7) showed a similar reactivity to \(\text{5f}\); that is, the reaction in benzene gave a mixture of several products. From the mixture, only a C-benzyl-NH product was isolated in low yield, but the position of the benzyl group was uncertain. \(\text{N}\)-Benzyllisatin (\(\text{5h}\), run 8) did not undergo debenzylation but two equivalents of benzene reacted at the 3-position to give 1-benzyl-3,3-diphenyloxindole in 88% yield. The reaction of isatin with aluminum chloride in benzene was reported to give the same kind of compound, 3,3-diphenyloxindole.\(^9\) Other indolic com-

a) High-resolution mass spectral data.

Compounds, N-benzyl-2-phenyl-1H-indole (5n), N-benzylloxindole (5o), and related heterocycles (5p and 5q) did not undergo debenzylation at all. On the other hand N-benzylbenzamide derivatives (5i, 5j, and 5k, runs 9—11) underwent debenzylation successfully. In them, a more electronenegative group on the benzene ring accelerated debenzylation. However, the N-methyl derivative of 5i (5u), phthalimide (5r), benzylanilides (5s and 5i), N-benzylidenediphenylamine (5v), ethyl N-benzylanthranilate (5w), and the N-acetyl derivative of 5w (5x) did not undergo debenzylation.

The effect of Lewis acids other than aluminum chloride, that is, boron trifluoride etharete, titanium chloride, stannic chloride, and ferric chloride, was examined. The reaction of ethyl 1-benzyl-1H-indole-2-carboxylate (1a, X = H) with the former three Lewis acids gave only recovered starting material, while the reaction with ferric chloride gave only a mixture of C-benzyl-NH products.

Finally, we examined the effect of a substituent on the benzyl group. Two kinds of ethyl 1-(p-substituted)benzylindole-2-carboxylate (5i and 5m), were allowed to react under the same debenzylation conditions. Although the p-nitrobenzyl group was not removed at all, the p-methoxybenzyl group was removed easily to the same extent as the benzyl group.²) Apparently a big substituent effect exists, suggesting that the stability of the benzyl cation (X=C₆H₄CH₂⁺) determines the rate of deprotection. However, as the extent of removal of p-methoxybenzyl and benzyl groups is at the same level, the benzyl group is better for practical use.

In conclusion, the present method can be reliably applied to benzyl derivatives of 2-acyl, 2-alkoxy carbonyl, and fully aromatized indoles, as well as some benzamides. Before we started the present examination, we had suspected that our method might be applicable only to 2-carboxyindoles, in which aluminum chloride could react easily with indolic nitrogen owing to assistance of the neighboring carbonyl group. The present result shows that the debenzylation does not require 2-carbonyl group assistance and thus is not restricted to 2-acycindoles. Though no assistance of the 2-carbonyl group was required for debenzylation, the presence of this group is expected to favor debenzylation to some extent by its weak coordination with aluminum chloride. The reaction seems to be influenced by the basicity and steric crowdedness of nitrogen, because basic compounds (5q, 5r, and 5w) did not undergo debenzylation, and N-alkyl-N-benzylbenzamides (5u) did not, while corresponding N-benzyl-NH-benzamides (5i, 5j, and 5k) did. This steric crowdedness would be responsible for the non-reactivity of 1-benzyl-2-phenyl-1H-indole (5n). Usual indoles (not stabilized indoles) and oxindoles are not suitable substrates for this debenzylation. Although N-benzyl derivatives of other heterocycles and other amides are usually hard to debenzylate, a trial of the debenzylation process is advisable for every N-debenzylation, as the reactions of some benzylbenzamides were successful. As to the solvent (which has a trapping ability for the benzyl cation formed), the relative merits of benzene and anisole cannot be explained straightforwardly. Anisole seems to be better than benzene for trapping the benzyl cation, whereas anisole would combine weakly with aluminum chloride in an acid–base interaction to weaken the reactivity of aluminum chloride. Generally speaking, benzene is recommended due to its general applicability and easy handling. It may be worth trying both in any particular case.

### Experimental
All melting points were measured on a micro melting point hot stage (Yanagimoto) and are uncorrected. IR spectra were recorded in Nujol mulls (unless otherwise stated) on a Shimadzu IR 400 instrument. ¹H-NMR spectra were recorded in CDCl₃ (unless otherwise stated) on a Hitachi R-24B spectrometer (60 MHz). In the ¹H-NMR spectra, chemical shifts are given in δ values referred to internal tetramethylsilane, and the assignment of all NH and OH signals was confirmed by the disappearance of their signals after addition of D₂O. Mass spectra (MS) were measured by the direct inlet system on JEOL JMS-01-GS-2 spectrometer. For column

$^a$ A = anisole, B = benzene. $^b$ Commercially available.

Compounds which did not undergo debenzylation were as follows.

![Chemical Structures](image)

**By-products**

![Chemical Structures](image)
chromatography, silica gel (Kiesel gel 60, 70–230 mesh, Merck), and for TLC, Kiesel gel GF 254, Merck were used. The abbreviations used are as follows: s; singlet; d; doublet; dd, double doublet; t; triplet; q; quartet; m, multiplet; br, broad; s, sharp.

**General Procedure for N-Benzylamino as Exemplified by Benzylation of 2-Phenylindole (5n)** A solution of 2-phenylindole (1.544 g, 8 mmol) in dimethylformamide (DMF) (15 ml) was added to a suspension of 60% NaH (0.32 g, 8 mmol) in DMF (10 ml) under ice-cooling and under an Ar atmosphere. The mixture was stirred for 0.5 h at 0 °C, and then benzylochloride (0.8 g) was added. The whole mixture was then added in 2 h at room temperature, poured into ice-water, and extracted with AcOEt. The organic layer was washed with 10% HCl, saturated NaHCO3, and brine, dried over MgSO4, and evaporated to dryness in vacuo. The residue was chromatographed on SiO2 with benzene-hexane (1:5) to afford colorless prisms (1.706 g, 75%), mp 96.5–98.5°C, which were recrystallized from AcOEt-water.

**General Procedure for Debenzylation of N-Benzyl Compounds** A solution of a benzyl compound (1.0 mmol) in benzene or anisole (1.1 mmol) was added to a suspension of AlCl3 (4–6 eq relative to the benzyl compound) in benzene or anisole (0.5–4.5 ml) under ice-cooling. The mixture was stirred under the conditions shown in Table III. The reaction mixture was poured into water and extracted with benzene or ethyl acetate. The organic layer was washed successively with 5% NaHCO3 and brine, dried over MgSO4, and evaporated to dryness in vacuo. The residue was chromatographed on SiO2 to give the NH-compound; a by-product was also obtained in some cases as shown in Table III.

**N-Benzyl-1-benzyl-1-H-indole-2-carboxylic acid (2a)** A solution of ethyl acetoacetate (2.469 g, 18 mmol) in DMF (5 ml) was added to a solution of 1-benzyl-1-H-indole-2-carboxylic acid (7) (2.057 g, 12 mmol) in DMF (4 ml). Then triethylamine (5.018 ml, 36 mmol) and diethylphosphorylcholine (DEPC) (3.362 g, 18 mmol) were added. The whole mixture was stirred at room temperature for 2 h, then poured into ice-water and extracted with AcOEt. The organic layer was washed with water, and extracted over MgSO4, and evaporated to dryness in vacuo. The residue was chromatographed on SiO2 with benzene-AcOEt to give colorless needles (2.49 g, 75%), which were recrystallized from benzene, mp 142–145.5 °C. Anal. Caled for C22H19NO: C, 77.67; H, 6.52; N, 10.06. Found: C, 77.90; H, 6.51; N, 10.04. IR ν max cm⁻¹: 3440 (NH), 1660 (C=O). H-NMR δ: -1.17 (3H, s, J=8-12Hz, CH3-C), 1.15–3.61 (2H, m, NCH2CH3), 5.77 (2H, s, NCH2), 6.10 (1H, brs, NH), 6.80 (1H, s, C=H), 6.90–7.70 (5H, m, arom H). MS m/z (％): 91 (100), 287 (M⁺, 52).

**3-Acetyl-1-benzyl-1-H-indole (5c)** Phosphorus oxychloride (1.4 ml, 15 mmol) was added dropwise to dimethylacetamide (DMAC, 6 ml) under ice-cooling. A solution of N-benzylindole (8) (1.036 g, 5 mmol) in DMAC (4 ml) was added to this solution, and the whole mixture was stirred at 95 °C for 2 h. A solution of NaOH (3.5 g) in water (10 ml) was added to the reaction mixture, and the whole mixture was stirred at 95 °C for 10 min, then extracted with AcOEt. The organic layer was washed with saturated NaCl, and dried over MgSO4, and evaporated to dryness in vacuo. The residue was recrystallized from hexane–CHCl3 to give colorless prisms (258 mg, 88%), mp 166–168 °C. Anal. Caled for C20H23NO: C, 86.37; H, 5.64; N, 3.73. Found: C, 86.13; H, 5.55; N, 3.64. IR ν max cm⁻¹: 1700 (C=O). H-NMR δ: 3.95 (2H, s, NCH3), 6.73–7.45 (19H, m, arom H). MS m/z (％): 254 (100), 375 (M⁺, 43).
