Quantitative Structure–Activity Relationships of Ca$$^{2+}$$-Antagonistic Semiotiadil Congeners

Ken-ichi Fujimura,* Atsushi Ota, and Yoichi Kawashima

Developmental Research Laboratories, Santen Pharmaceutical Co., Ltd., 9–19, Shimoshinjo 3-chome, Higashiyodogawaku, Osaka 533, Japan. Received August 10, 1995; accepted November 9, 1995.

Structure–Ca$$^{2+}$$ antagonistic activity relationships of semiotiadil (1) congeners having a benzothiazine cyclic system were studied quantitatively by the Hansch–Fujita method. A quadratic dependency of the activity on $\text{Cllog } P$, a lipophilic descriptor, of terminal aryalkylamine moieties was suggested. A correlation between the dipole moment component of the 5’-substituted 2-phenylbenzothiazine parts and the potency was also suggested. Additionally, quantitative analysis was successfully shown for the 2-substituted 1 congeners. The results gave information about the mode of binding of 1 with Ca$$^{2+}$$ receptor.

Key words semiotiadil; calcium antagonist; quantitative structure–activity relationships; lipophilicity; dipole moment; free energy

Semiotiadil (1) is a new non-dihydropyridine Ca$$^{2+}$$ antagonist with a 2-phenylbenzothiazine (2-PBT) skeleton. Its activity is vasoselective, potent and long-lasting, with few adverse effects. We have been studying the stereochemistry of 1 to clarify its structure–activity relationships. In this report, we present a study of quantitative structure–activity relationships (QSAR) of 1 and its analogs, using the Hansch–Fujita method.

Results

QSAR on the Arylalkylamine Side Chain Correlations between the Ca$$^{2+}$$-antagonistic activities of the compounds 1, 5—7, 9 (Table 1) and several physicochemical descriptors of the substituents on the distal aromatic rings were examined. These compounds were selected from those having simple substituents whose descriptor values have been reported. They all have (R)-configuration at C-2. These limitations would reduce perturbation of the antagonistic activity by physicochemical factors, and simplify the early stage of the analysis. The descriptors used are typical ones for QSAR analysis and can be categorized into electronic ($\sigma_p$, $\sigma_m$, $\sigma_a$, $\sigma_e$, $\sigma_{re}$, $F$, $R$), steric ($MR$, $Es$, $L$, $B_1$, $B_2$) and hydrophobic ($\pi$) types. A better correlation ($r=0.775$ (correlation coefficient)) of the activity was found with $\pi$ than with the others. Similar potency dependence ($r=0.783$) on the retention times in reversed-phase high-performance liquid chromatography was obtained for 6 compounds (1 (retention time = 5.90 min), 5 (6.61), 6 (5.62), 7 (8.82), 8 (12.13), 9 (8.48)). Since these results suggest the dependence of the activity on hydrophobicity of the substituents at the distal aromatic ring, we examined the QSAR with $\text{Cllog } P$, an empirically estimated log $P$ value, as a hydrophobic descriptor. This is because $\text{Cllog } P$ values can easily be calculated for diverse structures with a computer program.

Equation 1 (Eq. 1) was derived for compounds 1, 4—9, having (R)-configuration at C-2 of the benzothiazine skeleton. In this expression, $n$ represents the number of data, $s$ is the standard deviation, and the figures in parentheses are 95% confidence limits of the corresponding coefficients. The equation is highly significant in terms of the $F$ statistic ($F_{0.001}^1,50 = 47.18$).

\[
\text{plC}_{50} = -1.075(\pm 0.317)\text{Cllog } P + 11.902(\pm 1.779) \\
(n=7, r = 0.969, s = 0.223, F_{1,5} = 75.71)
\]

Observation of the activity distribution of the racemic compounds (2, 3, 10—17) revealed a quadratic relation of $\text{Cllog } P$ against the activity for a given number of methylene units ($m$). The coefficients of the parabolic regression equations of those relations were quite similar to each other, except for the location of $\text{Cllog } P_{\text{opt}}$ which gives the highest calculated activity from the quadratic regression equation. The disparity of $\text{Cllog } P_{\text{opt}}$ was about 0.53, being equal to the lipophilicity of one methylene unit. However, merging the two equations with an indicator variable expressing the difference of $m$ was unsuccessful. We then tried to combine the two equations using $\text{Cllog } P$ calculated for CH$_2$N(CH$_2$)$_n$CH$_2$CH$_2$CH$_2$ of Table 1, so as to eliminate the contribution of the lipophilicity of this one methylene unit (Eq. 2). In this equation, compound 13 was excluded since its inclusion gave a poor result. The steric effect of the two ortho methoxy substituents of the compound, that constrain the phenyl group rotation, may cause this irregularity.

\[
\text{plC}_{50} = -0.758(\pm 0.330)\text{Cllog } P^2 + 1.895(\pm 0.925)\text{Cllog } P + 5.557(\pm 0.580) \\
(n=9, r = 0.943, s = 0.077, F_{2,6} = 24.02, \text{Cllog } P_{\text{opt}} = 1.25)
\]

Since Eq. 1 and Eq. 2 cover $\text{Cllog } P$ ranges of 1.4—3.5 and 0.7—2.1, respectively, both equations were merged into one equation, except for 1 ($\text{Cllog } P$ values were from CH$_2$N(CH$_2$)$_n$CH$_2$CH$_2$CH$_2$-Z). Compound 13 was successfully included in this equation to give Eq. 3. Inclusion of compound 1 in Eq. 3 decreased the statistical significance, albeit there was still a fairly good correlation. Addition of an indicator variable that discriminates the optically active compounds from the racemic ones into the equation was not satisfactory. This may be a bias owing to the set of racemic compounds having smaller ranges of activity and $\text{Cllog } P$ to 1 than the optically active compounds.

\[
\text{plC}_{10} = -0.294(\pm 0.139)\text{Cllog } P^2 + 0.568(\pm 0.560)\text{Cllog } P + 6.334(\pm 0.494) \\
(n=16, r = 0.957, s = 0.177, F_{1,15} = 71.26, \text{Cllog } P_{\text{opt}} = 0.97)
\]

Fig. 1. Two Principal Conformations (A, B) of the 2-PBT Part of 1

**QSAR of the 5'-Substituted 1 Congeners** Several compounds (2, 18—21) having different functional groups at C-5' are shown in Table 1. Since their antagonistic activities seem to depend on some electronic features, many kinds of electronic parameters were applied for searching for correlations. The parameters included reported ones for the substituents\(^3\) or descriptors on the 2-PBT part calculated by the molecular orbital method\(^2\) or molecular mechanics method.\(^2\) Among the contingent descriptors (various Hammett's \(\sigma, F, R\), atomic charge, highest occupied molecular orbital (HOMO) or lowest unoccupied molecular orbital (LUMO) energy, atomic polarizability, superdelocalizability, chemical shifts of protons and so forth), the dipole moment vector \((DIP)\) was found to have some value as a descriptor. In particular, one component vector \((DIP_x)\) of the \(DIP\) was found to give a satisfactory equation (Eq. 4); the \(DIP_x\) vector runs roughly from C-2 to C-7 of the benzothiazine moiety.

\[
pIC_{50} = 0.535 (\pm 0.195) DIP_x + 6.287 (\pm 0.155) \\
(n = 5, r = 0.981, s = 0.102, F(1,3) = 75.95) \quad (4)
\]

**QSAR of the 2-Substituted 1 Congeners** Previously, we reported the qualitative structure-activity relationship of the 2-PBT part of 2 analogs having \(R^2\) \((2, 22—25)\) at C-2 (Table 1).\(^2\) The ratio of molar fractions \((Z_A, Z_B)\) between the two principal conformations A and B (Fig. 1) involving 2-phenyl group rotation, calculated by the modified neglect of diatropic overlap (MNDO) method, was suggested to correlate with \(Ca^{2+}\)-antagonistic activity. A greater contribution of B was expected to give higher activity. Quantitative treatment of the relationship could also be

Fig. 2. Relationship between Observed and Calculated (Eq. 6) \(Ca^{2+}\)-Antagonistic Activities (pIC\(_{50}\)) of Semotiadil Congeners (1—25)
done by assuming log $K$ (=$\log(Z_n/Z_A)$) is equivalent to the free energy difference between the two conformations (Eq. 5). Non-activity of compound 25, which has no B conformation ($Z_B=0$), would be consistent with this.

\[
p_{\text{IC}_{50}} = 0.362(\pm 0.198) \log K + 5.406(\pm 0.507) \\
(n = 4, r = 0.984, s = 0.117, F_{1,3} = 61.57)
\]

(5)

**QSAR of the Whole Molecules**  Three kinds of QSAR regression equations (Eqs. 3—5) were obtained for the distal aromatic part and 2- or S'-substituted 2-PBT part of I congeners. These equations were then merged into one equation (Eq. 6) (2—24). The correlations among the descriptors in Eq. 6 were insignificant except for the one between $C\log P$ and its quadratic term (Table 2). Figure 2 shows the relationship between the observed and calculated activities from Eq.6.

\[
p_{\text{IC}_{50}} = -0.306(\pm 0.128)(C\log P)^2 + 0.610(\pm 0.521)C\log P \\
+ 0.412(\pm 0.130)DIPx + 0.296(\pm 0.101)\log K + 4.847(\pm 0.638) \\
(n = 23, r = 0.955, s = 0.171, F_{4,18} = 46.86, C\log P_{\text{opt}} = 1.00)
\]

(6)

**Discussion**  Semoaldal analogs with diverse functional groups on their distal aromatic rings were found to have parabolic lipophilic dependency of their Ca$^{2+}$ antagonistic activities. In particular, $C\log P$ showed a very good correlation with the activities.

The optimum value of $C\log P$ ($C\log P_{\text{opt}}$) according to Eq. 3 or Eq. 6 was close to unity. The $C\log P$ value of the corresponding arylalkylamino side chain, that has a methylenedioxynhenoxy (MDP) group, of I is 1.40 (Table 1) being close to the $C\log P_{\text{opt}}$. Therefore, compound I is expected to have potent Ca$^{2+}$ antagonistic activity. There are some other potent compounds with comparable $C\log P$ and activity (Table 1) to I. Among those congeners, the MDP group was also reported to be preferable for vasocardsioselectivity.14)

In the compound set used to obtain Eqs. 1—3, most have substituted phenoxy groups as the terminal structure Z (Table 1). Compound 4, however, has a benzofturazanylamino group as Z. Also, a trimethoxyphenyl group was included in 10 or 11. The binding site of the receptor for those terminal groups, then, might accept more than simply substituted phenoxy groups via hydrophobic interaction. Alternatively, the lipophilic nature may play a role in passive permeation to the target receptor. Participation of lipophilicity in the permeation process has been suggested for other Ca$^{2+}$ antagonists.9)

The effect on the activity of the methylene units that link the 2-phenyl group and the tertiary amine in the compound set appeared insignificant, because it was not included explicitly in Eq. 2 or Eq. 3. In order to discuss the role of the methylene units for the activity, however, more compounds having different numbers (m) of units will be required.

Dipole properties have an important role in long-range ligand-receptor recognition and subsequent binding. Since the DIPx vector runs approximately from C-2 to C-7 of the 2-PBTs, one recognition site for the 2-PBT part of I derivatives in the receptor may have a counter dipole

---

Fig. 3. Stereoview of Three Possible Conformations (I, II, III) of I
nature to attract those antagonists electrostatically.

Equation 6 was obtained from Eqs. 3—5 without large perturbation of the coefficients of the original equations. Since the descriptors (DIPx, log K) in Eq. 4 and Eq. 5 were estimated with 2-phenylbenzothiazine model compounds that lack the long arylalkylamine side chain, these results suggest that the roles of the three physicochemical features in Eq. 6 in bringing about the antagonistic activities are not dependent on one another.

Molecular mechanics calculations, in a previous study, led us to propose three possible conformations (I, II, III) (Fig. 3) of I under a constraint of close proximity between the 2-phenyl ring and the MDP group, that was suggested by NMR spectrometry. Since there is no evidence regarding the active conformation of I in the Ca²⁺ receptor, we can consider these conformations as candidates for the active conformation.

Of the 3 possible conformations, II appears to be most acceptable as the active conformation. This is because the 2-aryalkylamine side chain bypasses the H-2 on the 2-PBT and thus allows the free rotation of the 2-phenyl group around the benzothiazine ring. In contrast, the aryalkylamine of I or III would affect the rotation of the 2-phenyl group. The free rotation of the 2-phenyl group is relevant to the molar fractions, Zₐ and ZₐB, which afford the descriptor, log K, in Eq. 5 and Eq. 6. In addition, the 2-PBT part of II is exposed and its dipole nature (DIPx) might be recognized by the receptor.

Experimental

Clog P values were estimated using MacLog P.4) The structures of the model compounds ((R)-2-2'-methoxy-5'-R'-phenylbenzothiazin-3-one) were obtained by optimization with semiempirical (PM3)4) and ab initio (STO-3G)4) molecular orbital methods. Dipole moment of each model compound was estimated for the global minimum structure (conformation B in Fig 1) by a computer program, QSR+.7) with the atomic charges assigned by QUANTA.1) Biological potencies were measured as reported elsewhere with isolated taenia caecum of guinea pig.4) Acknowledgment We thank Professor Toshimasa Ishida (Osaka University of Pharmaceutical Science) for his helpful suggestions.
