Chemistry of Zygomycin-A. I*1,2 Degradative Studies;
Pseudoneamine and d-Ribose.
(Research Laboratories, Takeda Chemical Industries, Ltd.*3)

In the previous report*3 it was mentioned that antibiotic No. 45449A belongs to the
neomycin group but differs from kanamycin, neomycin, or hydroxymycin,*3 and closely
resembles paromomycin*3 reported in the midst of the present work.

Further studies*3 revealed that antibiotic No. 45449A was different from paromomycin
in the diaminohexose moiety, and therefore the name zygomycin-A was assigned to this
antibiotic.

(1) Pseudoneamine

In the present paper are reported the isolation and identification of pseudoneamine and
d-ribose, which were separated from the degradation products of zygomycin-A.

Methanolsysis of zygomycin-A hydrochloride in 0.3N methanolic hydrogen chloride for
3 hours gave a crystalline hydrochloride (I), C_{12}H_{22}O_{4}N_{4}·3HCl. Hydrolysis of (I) by refluxing
with 6N hydrochloric acid for 1.5 hours gave two compounds, (II), C_{6}H_{12}O_{4}N and (III),
C_{6}H_{14}O_{2}N, which were purified by fractional crystallization or by ion exchanger chromatography. (II) was assumed to be an amino-sugar since it showed positive Elson–Morgan,
Ninhydrin, and Fehling tests. Identity of (II) with p-glucosamine was established by the
measurement of infrared spectrum, X-ray diffraction pattern, and specific rotation, as well as by mixed melting point determination.

(III) was positive to the Ninhydrin reaction but negative to the Elson–Morgan and Fehling
tests. This optically inactive compound proved to be identical with deoxystrepta-

Association, September 18, 1959, and January 22, 1960.
*3 Juso-Nishino-cho, Higashiyodogawa-ku, Osaka (人見 弘、鳥井 聡、山崎 勤、三宅 彰).
mine$^{5-6}$ produced from neomycin and kanamycin, since its infrared absorption spectrum and X-ray diffraction pattern were the same as those of an authentic sample and it showed no depression in melting point when mixed with an authentic sample. N,N',N"-Triacetyl derivative of (I), prepared by the method of Roseman and Ludowieg,$^7$ consumed two moles of periodate in acetate buffer of pH 4.2, producing no formic acid.

These data, coupled with its infrared spectrum, suggested that (I) was identical with pseudoneamine produced from hydroxymycin and paromomycin. Fig. 1 shows the infrared absorption spectrum of pseudoneamine trihydrochloride.

![Fig. 1. Infrared spectrum of Pseudoneamine Trihydrochloride](image)

From the filtrate from pseudoneamine trihydrochloride, amorphous methyl zygobiosaminide, a moiety of the methylglycoside molecule, was obtained by fractional precipitation and purification by chromatography on alumina or carbon. It was positive to Ninhydrin reaction but negative to Elson-Morgan and aniline hydrophenalate tests.

Hydrolysis of methyl zygobiosaminide with dilute hydrochloric acid for 2.5 hours at 100$^\circ$ produced zygobiosamine, which afforded p-ribose and diaminoheXose$^9$ on further hydrolysis.

This disaccharide gave positive Fehling and aniline hydrophenalate reactions.

Methyl zygobiosaminide was N-acetylated by the method of Roseman and Ludowieg,$^7$ affording amorphous methyl N,N'-diacetylzygobiosaminide, C$_{11}$H$_9$O$_6$N$_3$(OCH$_3$)$_2$(COCH$_3$)$_2$.

The product was hydrolyzed with dilute sulfuric acid and the treatment of the reaction mixture with barium carbonate, followed by chromatography on ion exchange resin and carbon, afforded a crystal clear neutral carbohydrate, which was in accord with p-ribose in color test, papergram, specific rotation, and infrared absorption spectrum.

Identity of the carbohydrate with p-ribose was also afforded by the fact that it gave crystalline ribitol, m.p. 98-100$^\circ$, by reduction with sodium borohydride.

**Experimental**

Isolation of Pseudoneamine Trihydrochloride—A solution of 5 g. of zygomycin-A hydrochloride in 560 cc. of 0.3N MeOH-HCl was refluxed for 3 hr., during which a crystalline precipitate deposited. After refrigerating overnight, the precipitate consisting of the trihydrochloride of pseudoneamine was collected by filtration and purified by recrystallization from hydr. EtOH, m.p. 232$^\circ$ (decomp.), $[\alpha]_D^{20}$ +83$^\circ$ (c=0.5, H$_2$O). Anal. Calcd. for C$_{11}$H$_9$O$_6$N$_3$·3HCl·H$_2$O: C, 31.98; H, 6.71; N, 9.32. Found: C, 31.70; H, 6.66; N, 9.28.

Preparation of Free Base of Pseudoneamine—A solution of pseudoneamine trihydrochloride was passed through a column of Dowex 1 (OH$^-$ form). The effluent and washings were concentrated in vacuum, and EtOH was added to the residue until the solution became cloudy. This was allowed to cool in an ice box, affording the crystalline free base of pseudoneamine, m.p. 250-251$^\circ$ (decomp.), $[\alpha]_D^{20}$ -124$^\circ$ (c=1, H$_2$O). Anal. Calcd. for C$_{11}$H$_9$O$_6$N$_3$·$\frac{1}{2}$H$_2$O: C, 43.36; H, 7.88; N, 12.64. Found: C, 43.69; H, 8.13; N, 12.93.

Preparation of N,N',N"-Triacetylpseudoneamine—Pseudoneamine trihydrochloride was N-acetylated by the method of Roseman and Ludowieg.$^7$ The product was crystallized from AcOH, m.p.

Isolation of Deoxystreptamine Dihydrochloride——Pseudoneamine trihydrochloride (1 g.) was dissolved in 8.5 cc. of conc. HCl and the solution was refluxed for 2.5 hr. The hydrolysate was concentrated in vacuo and Me₂CO was added to the residue, affording a brown amorphous powder (0.99 g.). A solution of this material in water (4 cc.) was treated with carbon and, after addition of EtOH (25 cc.), allowed to cool in an ice box. The resulting white crystals were collected by filtration and recrystallized from hydr. EtOH. The infrared absorption spectrum and X-ray diffraction pattern of the product were identical with those of deoxystreptamine, m. p. 325° (decomp.), [α]D 0° (c=0.5, H₂O), derived from kanamycin. Anal. Caled. for C₁₇H₂₈O₇N₃·2HCl: C, 37.65; H, 6.86; N, 11.92. Found: C, 37.61; H, 6.83; N, 12.00.

Isolation of L-Glucosamine Hydrochloride——To the mother liquor from deoxystreptamine hydrochloride, 10 cc. of MeOH and 25 cc. of Me₂CO were added. The resulting precipitate was removed by filtration and to the filtrate were added 50 cc. of Me₂CO and 50 cc. of Et₂O, affording crystalline D-glucosamine hydrochloride. It was recrystallized from hydr. EtOH. The infrared spectrum and X-ray diffraction pattern of the product were identical with those of authentic D-glucosamine hydrochloride, m. p. 188°~209° (decomp.). [α]D 29°~+72° (c=1, H₂O). Anal. Caled. for C₆H₁₄O₅N₂·HCl: C, 33.42; H, 6.56; N, 6.50. Found: C, 33.25; H, 6.67; N, 6.71.

Isolation of Methyl Zygobosaminine Dihydrochloride——The mother liquor from pseudoneamine trihydrochloride was concentrated in vacuo and the concentrate was subjected to fractional precipitation with Et₂O, affording a white amorphous powder.

The product (1.47 g.) was purified by dissolving it in MeOH-Et₂O mixture (2:1) (150 cc.) and passing the solution through a column of alumina (50 g.), followed by eluting with a MeOH-Et₂O mixture (5:2). The methyl zygobosaminine thus purified was collected by evaporating the effluent to a small amount in vacuo and adding Et₂O to the residue. [α]D 29° (c=1.0, H₂O).

Preparation of Methyl N,N'-Diacetylyzgobiosaminide——Methyl zygobosaminine dihydrochloride was N-acetylated by the method of Roseman and Ludowig, affording the desired product as a hygroscopic amorphous powder. Anal. Caled. for C₁₇H₂₈O₇N₃(COCH₃)₂(CH₃O): C, 47.11; H, 6.91; N, 6.86. Found: C, 46.70; H, 6.99; N, 6.68.

Isolation of D-Ribose from Methyl N,N'-Diacetylyzgobiosaminide——A solution of methyl N,N'-diacetylyzgobiosaminide in 0.1N H₂SO₄ was heated under reflux for 3.5 hr. After cool, the hydrolysate was neutralized with BaCO₃ and the resulting precipitate was collected and washed. The filtrate and washings were combined and passed successively through columns of Amberlite IR-120 (H⁺ form) and IRA-400 (OH⁻ form). The effluent and washings were concentrated in vacuo and the concentrate was passed through a column of charcoal. The Fehling test-positive fraction was collected, concentrated to a syrup in vacuo, and EtOH was added. The mixture was allowed to stand in an ice box, affording white crystals, m. p. 86°. The infrared spectrum of the product was identical with that of D-ribose and it showed no depression in melting point on admixture with an authentic sample.

Since the sugar exhibited a specific rotation, [α]D 12°→−17° (24 hr.) (c=1.0, H₂O), it was assumed to belong to the D-series.

Reduction of D-Ribose with Sodium Borohydride——The colorless syrup prepared by the procedure above was reduced with NaBH₄ and the reaction mixture was passed successively through columns of Amberlite IR-120 (H⁺ form) and Amberlite IRA-400 (OH⁻ form) to remove inorganic impurities. The effluent and washings were evaporated to a syrup, which was allowed to stand in an ice box with addition of EtOH, affording white crystals, m. p. 98°~100°. The infrared spectrum of the product was identical with that of ribitol and there was observed no depression in melting point on admixture with an authentic sample. Anal. Caled. for C₆H₁₂O₅: C, 39.47; H, 7.95. Found: C, 39.93; H, 7.93.

The authors are grateful to Dr. Satoru Kuwada, Director of the Laboratories, for his encouragement throughout the present work and for his generosity in permitting the publication of the results.

Summary

Zygomycin-A, when subjected to methanolysis, produced a crystalline pseudoneamine trihydrochloride and amorphous methyl zygobosaminide dihydrochloride (C₁₇H₁₄O₇N₃(OCH₃)₂·2HCl). Methyl-N,N'-diacetylyzgobiosaminide on hydrolysis yielded D-ribose.
