Summary: The Chinese prescription Kangen-karyu, comprised of six crude drugs, has received much attention due to its numerous biological activities. The present study was conducted to examine whether Kangen-karyu has an ameliorative effect on dyslipidemia. The effect of Kangen-karyu was evaluated using 3T3-L1 adipocytes, and also db/db mice as an experimental model for diabetic dyslipidemia. Kangen-karyu significantly inhibited adipocyte differentiation and lipid accumulation. Kangen-karyu also down-regulated the mRNA levels of peroxisome proliferator-activated receptor (PPAR)γ, sterol regulatory element-binding protein (SREBP)-1c, and fatty acid synthase, and the protein levels of aP2 and PPARγ, which indicates that Kangen-karyu inhibited adipogenesis during adipocyte differentiation, and may have potential anti-dyslipidemia effects. In addition, the administration of Kangen-karyu reduced hyperlipidemia in db/db type 2 diabetic mice through a decline in the serum levels of lipids, and an improvement of lipoprotein profiles. The enhanced hepatic triglyceride level of the db/db mice was significantly reduced by Kangen-karyu administration through the down-regulation of SREBP-1 and lipogenic enzymes in the liver. These findings indicate that Kangen-karyu exerts anti-dyslipidemia effects in adipocytes and type 2 diabetic db/db mice.

Keywords: Kangen-karyu, 3T3-L1 adipocyte, db/db mouse, dyslipidemia

1. Introduction

Metabolic syndrome is a multi-component disorder characterized by hypertriglyceridemia, hyperglycemia, abdominal obesity and hypertension, and is closely linked to type 2 diabetes mellitus (1, 2). The etiology of metabolic syndrome involves the complex interaction between genetic, metabolic, and environmental factors (3). Obesity is well recognized as the most important health problem related to the genesis of metabolic syndrome, and the rising incidence of this disease throughout the world has generated interest in the underlying mechanisms involved in these pathologies (4).

Obesity is caused by an imbalance between energy intake and expenditure that may lead to the pathological growth of adipocytes (5). Adipocytes play a central role in regulating adipose mass and obesity. Increased adipose mass in obesity is not only caused by adipose tissue hypertrophy, but also by adipose tissue hyperplasia, which triggers the transformation of preadipocytes into adipocytes (6, 7). Thus, adipocyte differentiation and the amount of fat accumulation are associated with development of obesity. On the other hand, dysfunctional lipid metabolism is a key component in the development of metabolic syndrome, a very common condition characterized by dyslipidemia, insulin resistance, abdominal obesity, and hypertension, which are all related to an elevated risk of type 2 diabetes mellitus (8). The liver is an important organ for maintaining lipid metabolism and homeostasis, since it can store (via lipogenesis) or release (as lipoprotein) lipid fuels. Triglycerides (TG) are involved in the ectopic accumulation of lipid
stores in the liver and are associated with a number of diseases, such as metabolic syndrome and type 2 diabetes.

Anti-obesity drugs such as orlistat, sibutramine, and topiramate have been used to treat obesity (9). However, these drugs have many side effects, including dry mouth, anorexia, insomnia, and gastrointestinal distress (10). Due to the adverse side effects associated with many anti-obesity drugs, recent drug trials have focused on herbal medicines (11). Under the guidelines of the US Food and Drug Administration, botanical drugs can be developed faster and more cheaply than conventional single-entity pharmaceuticals. Thus, there are many botanicals that might provide safe, natural, and cost-effective alternatives to synthetic drugs. Recent studies have found that natural bioactive compounds can be used to treat obesity in 3T3-L1 adipocytes and in an obese mouse model.

Kangen-karyu (Guan-Yuan-Ke-Li), a crude drug developed from a traditional Chinese prescription consisting of six herbs (Paeoniae Radix, Cnidii Rhizoma, Carthami Flos, Cyperi Rhizoma, Aucklandiae Radix, and Salviae Miltiorrhizae Radix), has been clinically used as a treatment for cardiovascular diseases, such as angina pectoria and cerebrovascular diseases. Kangen-karyu shows biological activity, such as an anti-aging effect, the inhibition of platelet aggregation, a hypotensive effect, and the recovery of learning and memory impairment induced by senescence (12-15). In addition, we have reported that Kangen-karyu showed favorable ameliorative effects on fructose-induced metabolic syndrome, such as hyperglycemia, hyperlipidemia, and hypertension, through the reduction of TG and cholesterol levels with the regulation of hepatic sterol regulatory element-binding protein (SREBP)-1 expression, and with the regulation of hepatic sterol regulatory through the reduction of TG and cholesterol levels as hyperglycemia, hyperlipidemia, and hypertension.

2. Materials and Methods

2.1. Materials

Dulbecco’s modified Eagle’s medium (DMEM), fetal calf serum (FCS), penicillin, streptomycin, and phosphate-buffered saline (PBS) were purchased from HyClone Laboratories (Logan, UT, USA). 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide (MTT), insulin, dexamethasone, 3-isobutyl-1-methylxanthine (IBMX), oil red O, 2-mercaptoethanol, protease inhibitor cocktail, and β-actin were purchased from Sigma-Aldrich (St Louis, MO, USA). Primary antibodies against peroxisome proliferator-activated receptor (PPAR)γ, PPARα, and SREBP-1c were purchased from Santa Cruz Biotechnology (Santa Cruz, CA, USA). Similarly, secondary antibodies for mouse (peroxidase-conjugated affinipure goat anti-mouse IgG) and rabbit (peroxidase-conjugated affinipure goat anti-rabbit IgG) were purchased from Jackson ImmunoResearch Laboratories (Baltimore, USA). The protein molecular weight marker was obtained from Thermo Scientific (Rockford, IL, USA). The nitrocellulose membrane for Western blotting was purchased from Bio-Rad Laboratories (Richmond, CA, USA). Western blot chemiluminescent substrate was purchased from Bio-Tek (Winooski, VT, USA). Radioimmunoprecipitation assay buffer was purchased from Bio-Rad Laboratories (Richmond, CA, USA). ECL Western Blotting Detection Reagents were purchased from GE Health Care (Piscataway, NJ, USA). All solvents, chemicals, and reagents were of analytical grade and purchased from Sigma-Aldrich unless otherwise specified.

2.2. Preparation of Kangen-karyu extract

The composition of Kangen-karyu used in this study is shown in Table 1. Kangen-karyu was as follows (values indicate proportions of each ingredient, expressed in parts per whole): Paeoniae Radix 2, Cnidii Rhizoma 2, Carthami Flos 2, Cyperi Rhizoma 1, Aucklandiae Radix 1, Salviae Miltiorrhizae Radix 4. These six crude drugs were boiled gently in 25 times their volume of water at 100°C for 1 h. After filtration, the solution was evaporated under reduced pressure to give an extract at a yield of 44%, by weight, of the

starting materials. The extract was dissolved in 50% aqueous ethanol with sonication, and filtered through a Cosmonice filter (PVDF, 0.45 μm; Nakalai Tesque, Kyoto, Japan). Reverse-phase high-performance liquid chromatography was performed using a Cosmosil 5C18-AR II column (250 × 4.6 mm i.d.; Nakalai Tesque) with elution gradients of 4-30% (39 min) and 30-75% (15 min) CH3CN in 50 mM H3PO4 at a flow rate of 0.8 mL/min. The UV absorbance from 200 to 400 nm was monitored with a Jasco MD-910 photodiode array detector (Jasco, Tokyo, Japan). All assigned peaks were identified by co-injection tests with authentic samples and comparing with UV spectral data. The major compounds detected were paeoniflorin, pentagalloyl glucose, rosmarinic acid, lithospermic acid, and lithospermic acid B. A voucher specimen has been deposited in the herbarium of the University of Toyama.

2.3. Culture cell experiments

2.3.1. Cell culture and differentiation

3T3-L1 preadipocytes were obtained from the American Type Culture Collection (Manassas, VA, USA) were cultured in DMEM containing 10% FCS, 100 μg/mL streptomycin, 100 U/mL penicillin, 44 mM NaHCO3, and 1 mM sodium pyruvate at 37°C under a 5% CO2 atmosphere. To induce differentiation, 3T3-L1 preadipocytes were cultured until confluence was reached (day 0), and the culture medium was replaced with a fresh induction medium containing 5 μg/mL insulin, 0.5 mM IBMX, and 1 μM dexamethasone in DMEM with 10% FCS for 2 days. The medium was then replaced with a differentiation medium containing 5 μg/mL insulin only and DMEM medium containing 10% FCS every 2 days for 8 days until the cells were harvested. To examine the effect of Kangen-karyu on adipogenesis, the extract was dissolved in the differentiation medium, and the medium was immediately processed into a sterile container by membrane filtration with a 0.22-μm filter. The culture medium was replaced with a fresh induction medium containing 5 μg/mL insulin, 0.5 mM IBMX, and 1 μM dexamethasone in DMEM with 10% FCS for 2 days. The medium was then replaced with a differentiation medium containing 5 μg/mL insulin only and DMEM medium containing 10% FCS every 2 days for 8 days until the cells were harvested. To examine the effect of Kangen-karyu on adipogenesis, the extract was dissolved in the differentiation medium, and the medium was immediately processed into a sterile container by membrane filtration with a 0.22-μm filter (EMD Millipore, MA, USA).

2.3.2. MTT assay

3T3-L1 preadipocytes were seeded at a density of 4 × 104 cells/well in a 96-well plate. After 4 h, Kangen-karyu extract at concentrations of 25, 50, 125, and 250 μg/mL was added to each well and incubated for 24 h. MTT solution (2 mg/mL) was added to each 96-well plate and incubated for 4 h, and then the medium containing MTT solution was removed. The formazan crystals in the viable cells were solubilized with dimethyl sulfoxide (150 μL), and absorbance was determined at 540 nm with a Microplate Reader (Immuno Mini NJ-2300; BioTec, Tokyo, Japan).

2.3.3. Oil red O staining

Intracellular lipid accumulation was measured using oil red O staining. The mature 3T3-L1 adipocytes were washed with PBS, fixed with 10% formalin (pH 7.4) for 30 min, and stained with oil red O solution for 1 h. The fat droplets in 3T3-L1 adipocytes were observed by phase contrast microscopy.

2.3.4. Western blot analysis

3T3-L1 adipocytes, cultured in 6-well plates, were treated with Kangen-karyu extract for 8 days and harvested using PRO-PREP™ protein extraction solution (iNtRON Biotechnology, Seoul, Korea). Cell debris was removed by centrifugation and the protein quantity in the lysate was determined using Bradford reagent (Bio-Rad Laboratories, Hercules, CA, USA). Cell lysates containing 30 μg of protein were separated using sodium dodecylsulfate polyacrylamide gel (SDS-PAGE) electrophoresis and transferred to nitrocellulose membranes, and the membranes were blocked with a solution of 0.1% Tween 20 in Tris-buffered saline containing 5% skim milk for 1 h at room temperature followed by overnight incubation with primary antibody at 4°C. After overnight incubation, the membranes were incubated with horseradish peroxidase-conjugated secondary antibody for 1 h at room temperature. Finally, protein bands were detected using the chemiluminescent substrate and VisionWorks™LS (Analysis Software, Upland, CA, USA).

2.3.5. Quantitative real-time polymerase chain reaction (PCR)

Total RNA was isolated from cells using Tri Reagent (Molecular Research Center, Cincinnati, OH, USA) and quantified using NanoDrop (Thermo Scientific, Wilmington, DE, USA). Fifty ng of isolated RNA was added to a final 30-μl volume of the Diastar™ 2X One Step RT-PCR kit (SolGent, Daejeon, Korea) with each primer: PPARγ, forward sequence 5'-ACC ACG-3', reverse sequence 5'-TAG AAG CAT TTG CAC-3', fatty acid synthase (FAS), forward sequence 5'-CAC TTC TGG AGA CAT CGC TCA GCG GGA AGG ACT TTA TG-3', SREBP-1c, forward sequence 5'-CAC TTC TGG AGA CAT CGC TCA GCG GGA AGG ACT TTA TG-3', reverse sequence 5'-GTT TGC TCG GAA TAT CCA GCC GCA TC-3', reverse sequence 5'-GGT TGC TCG GAA TAT CCA GCC GCA TC-3', reverse sequence 5'-CTG CGG AAA CTT CAG GAA ATG-3', reverse sequence 5'-GTT TGC TCG GAA TAT CCA GG-3'. The temperature cycle for the PCR reaction was 50°C for 30 min, 95°C for 15 min, and 30 cycles of [denaturation at 95°C × 1 min, annealing at 58°C (PPARγ, SREBP-1c, and β-actin) and 55°C (ACT) × 1 min] followed by final denaturation at 95°C for 5 min. β-Actin of the forward sequence 5'-ACC ACT CGC ATT CCT TTG AC-3', reverse sequence 5'-TCA GCG GGA AGG ACT TTA TG-3'; SREBP-1c, forward sequence 5'-CAC TTC TGG AGA ACA ACA GCC GCA TC-3', reverse sequence 5'-TGG TAG AGA ACA ACA GCC GCA TC-3', fatty acid synthase (FAS), forward sequence 5'-CTG CGG AAA CTT CAG GAA ATG-3', reverse sequence 5'-GTT TGC TCG GAA TAT CCA GG-3'. The temperature cycle for the PCR reaction was 50°C for 30 min, 95°C for 15 min, and 30 cycles of [denaturation at 95°C × 1 min, annealing at 58°C (PPARγ, SREBP-1c, and β-actin) and 55°C (FAS) × 1 min and extension at 72°C for 1 min] followed by final denaturation at 72°C for 5 min. β-Actin of the forward sequence 5'-TGC CAC TTT ATG AGG GTT ACG-3', reverse sequence 5'-TAG AAG CAT TTG
CGG TGC ACG-3', and the reaction cycle was as mentioned above. The obtained PCR products were analyzed in nucleic acid staining solution (Red Safe, iNtRON, Korea)-stained agarose (1.5%) gel by using VisionWorks™ LS UVP (Analysis Software, Upland, CA, USA).

2.4. Animal experiments

2.4.1. Experimental animals and treatment

The 'Guidelines for Animal Experimentation' approved by the University of Toyama were followed in the present study (Registration No.: S-2006 INM-22). Male, 5-wk-old, C57BLKS/J db/db mice and their age-matched, non-diabetic m/m littermates were purchased from Japan SLC (Hamamatsu, Japan). They were kept in a plastic-bottomed cage and exposed to a 12-h light/dark cycle. Room temperature (about 25°C) and humidity (about 60%) were controlled automatically. The mice were allowed free access to laboratory pellet chow (CLEA Japan, Tokyo, Japan, comprising 24.0% protein, 3.5% lipids, and 60.5% carbohydrate) and water was given ad libitum. After adaptation, glucose and TG levels of blood taken from the tail vein were measured, and then db/db mice were divided into three groups. The treatment with Kangen-karyu was initiated after confirming the induction of hyperglycemia and hyperlipidemia in the db/db mice, based on the presence of serum glucose 300 ± 10 mg/dL and serum TG 160 ± 5 mg/dL, respectively. The db/db vehicle group (n = 8) was orally given water, while the other two groups (n = 8 per group) were orally administered Kangen-karyu extract every day for 18 weeks at a dose of 100 mg or 200 mg/kg body weight, respectively. The non-diabetic m/m mice (n = 6) as a normal group were compared with the diabetic groups. When the db/db mice reached 24 weeks old, they showed reduced blood glucose, β-cell necrosis, and diminished hyperinsulinemia (21). Therefore, we decided on the time-point for the cessation of treatment as 24 weeks old in db/db mice.

2.4.2. Measurement of serum parameters

Glucose, TG, total cholesterol, and non-esterified fatty acids (NEFA) were measured using a commercial kit (Glucose CII-Test, Triglyceride E-Test, Cholesterol E-Test, and NEFA C-Test from Wako Pure Chemical Industries, Osaka, Japan). Leptin and insulin (Morinaga Institute of Biological Science, Yokohama, Japan) levels were measured based on enzyme-linked immunosorbent assays. High-density lipoprotein (HDL), low-density lipoprotein (LDL), and very low-density lipoprotein (VLDL) cholesterol distributions were measured using a BioVision kit (BioVision, Mountain View, CA, USA). Alanine aminotransferase (ALT) and aspartate aminotransferase (AST) were determined using a commercial reagent: GPT-UV Test Wako (Wako Pure Chemical Industries).

2.4.3. Measurement of hepatic TG content

The liver of each mouse was homogenized and total lipids of the liver homogenates were extracted with a mixture of chloroform and methanol (2:1, v/v) according to the method of Folch et al. (22). Then, the amount of TG was determined using commercial kits, as described previously.

2.4.4. Preparation of nuclear fraction

To prepare nuclear fractions, hepatic tissues were homogenized with ice-cold lysis buffer containing 5 mM Tris-HCl (pH 7.5), 2 mM MgCl2, 15 mM CaCl2, and 1.5 M sucrose, and then 0.1 M dithiothreitol (DTT) and protease inhibitor cocktail were added. After centrifugation (10,500 × g for 20 min at 4°C), the pellet was suspended with extraction buffer containing 20 mM 2-[4-(2-hydroxyethyl)-1-piperazyl] ethanesulfonic acid (pH 7.9), 1.5 mM MgCl2, 0.42 M NaCl, 0.2 mM EDTA, and 25% (v/v) glycerol, and then 0.1 M DTT and protease inhibitor cocktail were added. The mixture was placed on ice for 30 min. The nuclear fraction was prepared by centrifugation at 20,500 × g for 5 min at 4°C. The protein concentration was determined using a commercial kit (Bio-Rad Laboratories, Hercules, CA, USA).

2.4.5. Western blot analyses

For the determination of PPARα and SREBP-1, 10 μg of protein of each nuclear fraction was electrophoresed through 8% SDS-PAGE. Separated proteins were transferred to a nitrocellulose membrane, blocked with 5% (w/v) skim milk solution for 1 h, and then incubated with primary antibodies to PPARα, SREBP-1, and histone, respectively, overnight at 4°C. After the blots were washed, they were incubated with anti-rabbit or anti-mouse IgG horseradish peroxidase-conjugated secondary antibody for 1.5 h at room temperature. Each antigen-antibody complex was visualized using ECL Western Blotting Detection Reagents and detected by chemiluminescence with LAS-4000 (Fujifilm, Tokyo, Japan). Band densities were determined using ATTO Densitograph Software (ATTO Corporation, Tokyo, Japan) and quantified as the ratio to histone.
2.4.6. PCR

Total RNA was isolated from hepatic tissue using Trizol reagent (Invitrogen Life Technologies, Carlsbad, CA, USA) and quantified using NanoDrop (Thermo Scientific, Wilmington, DE, USA). The cDNAs were synthesized from 5 μg of RNA employing reverse transcriptase (Qiagen, Tokyo, Japan). For the real-time PCR, triplicate aliquots of serially diluted cDNA samples were used in a reaction mixture that contained 1 mM of each primer in a reaction volume of 50 μL employing the SYBR Green Real-time PCR kit (Qiagen) using a fluorometric thermal cycler (Mx3000P\textsuperscript{TM}; Stratagene, La Jolla, CA, USA). Reaction mixtures were incubated for an initial denaturation at 95°C for 15 min, followed by 45 cycles of 94°C for 15 s, 60°C for 30 s, and 72°C for 30 s. Primers used were as follows: acetyl-CoA carboxylase (ACC, sense: CCCAGCAGAATAAAGCTACTTTGG, antisense: TCTCTTTGTGCAACTAGGAACGT), FAS (sense: CCTGGATAGCATTCCGAACCT, antisense: AGCACATCTCGAAGGCTACACA). Glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was used as an endogenous control. The DCT method was employed for relative quantification. The DCT value for each sample was determined by calculating the difference between the CT value of the target gene and that of the GAPDH reference gene. The normalized target gene expression level in the sample was calculated using the formula $2^{-\Delta\Delta CT}$ as the fold change over the control.

2.5. Statistical analysis

Data are expressed as mean values with their standard errors. Statistical comparisons were performed by one-way ANOVA followed by Duncan's multiple-range test. Statistical analysis was conducted using SAS (release 9.2; SAS Institute, Cary, NC, USA) and $p < 0.05$ was considered significant.

3. Results

3.1. Culture cell experiments

3.1.1. Cell viability

To test the cytotoxic effects, MTT assays were conducted after treatment with various concentrations of Kangen-karyu during the adipogenesis of 3T3-L1 cells. The results of the MTT assay showed that Kangen-karyu did not decrease the cell viability up to the concentration of 250 μg/mL, as shown in Figure 1. Orlistat, which inhibits the absorption of neutral lipids and cholesterol by specifically inhibiting lipase (23), at a concentration of 20 μM (10 μg/mL) did not affect the cell viability.

3.1.2. Lipid accumulation

As shown in Figure 2A, Kangen-karyu significantly inhibited the accumulation of lipid droplets at a concentration of 50 and 250 μg/mL. As the main components of fat droplets are lipids in the form of TG, the TG contents of cells were determined. As shown in Figure 2B, Kangen-karyu reduced TG accumulation. When the 3T3-L1 cells were treated with orlistat, TG accumulation was reduced by 36% at a concentration of 20 μM.

3.1.3. PPARγ and aP2 protein expressions

As shown in Figure 3, the levels of PPARγ (A) and aP2 (B) were significantly inhibited by treatment with both
50 and 250 μg/mL Kangen-karyu. The effects of Kangen-karyu on PPARγ were more prominent than those of aP2.

3.1.4. PPARγ, SREBP-1c, and FAS mRNA expressions

The treatment with Kangen-karyu at 250 μg/mL led to a significant inhibition of PPARγ, SREBP-1c, and FAS mRNA expressions, as shown in Figure 4. In particular, the effect of PPARγ was marked and distinct from those of the other mRNA expressions.

3.2. Animal experiments

3.2.1. Body weight, food intake, and water intake

The db/db mice displayed typical phenotypes of obesity-induced diabetes with a marked increase in body weight gain, food intake, and water intake, as compared with m/m mice (normal control). The gain of body weight in db/db mice was non-significantly decreased by Kangen-karyu administration. The food and water intakes in db/db mice were significantly decreased by 100 mg/kg of Kangen-karyu treatment.

3.2.2. Hematological analyses

All serum constituents were elevated in vehicle-treated db/db mice compared with m/m mice. As shown in Table 2, Kangen-karyu 200 mg/kg-administered db/db mice groups showed decreased serum glucose and leptin, but no alteration of insulin. Furthermore, the administration of Kangen-karyu to db/db mice significantly improved TG, LDL/VLDL cholesterol, and NEFA compared with the db/db control group. Regarding hepatic function parameters, serum ALT and AST levels in vehicle db/db mice were elevated compared with those in m/m mice, while, in Kangen-karyu-administered db/db mice, these two parameters were slightly decreased.

3.2.3. Hepatic TG content

Compared with m/m mice, the liver weight of db/db mice was significantly augmented, but the administration of Kangen-karyu led to a significant decrease in its weight. Concerning the hepatic content of TG, the db/db control group showed a marked increase compared with the m/m group. This TG

Figure 3. PPARγ and aP2 protein expressions in 3T3-L1 adipocytes. Representative immunoblots for (A) PPARγ and (B) aP2. Immunoblotting analyses were performed as described in Materials and Methods. Cont, control; K50, Kangen-karyu 50 μg/mL; K250, Kangen-karyu 250 μg/mL; O20, orlistat 20 μM. Data are the mean ± S.E.M. Bars with the same letter are not significantly different by Duncan’s multiple range tests ($p < 0.05$).

Figure 4. PPARγ, SREBP-1c, and FAS mRNA expressions in 3T3-L1 adipocytes. Representative immunoblots for (A) PPARγ, (B) SREBP-1c, and (C) FAS. Immunoblotting analyses were performed as described in Materials and Methods. Cont, control; K250, Kangen-karyu 250 μg/mL. Data are the mean ± S.E.M. Bars with the same letter are not significantly different by Duncan's multiple range tests ($p < 0.05$).
content was significantly decreased by Kangen-karyu administration at a dose of 100 and 200 mg/kg body weight/day, as shown in Table 3.

3.2.4. Hepatic PPARα and SREBP-1 protein expressions

As shown in Figure 5B, protein expression of hepatic SREBP-1 was markedly increased in the db/db control group compared with the m/m group. The administration of Kangen-karyu at 100 and 200 mg/kg led to a significant down-regulation of SREBP-1 expression. While, in the case of hepatic PPARα, no significant difference among the groups was observed (Figure 5A).

3.2.5. Hepatic mRNA expressions involved in TG metabolism

The effects of Kangen-karyu administration on the mRNA levels of genes involved in lipid metabolism in the hepatic tissue are presented in Figure 6. Over-expressions of ACC and FAS mRNA were seen in hepatic tissue of the db/db vehicle group compared with m/m group. On the other hand, the administration of Kangen-karyu at a dose of 200 mg/kg body weight/day significantly inhibited the expressions of ACC and FAS in db/db mice.

m/m, Misty mice; db/db-Veh, db/db vehicle-treated mice; db/db-K100, db/db Kangen-karyu (100 mg/kg body weight)-treated mice; db/db-K200, db/db Kangen-karyu (200 mg/kg body weight)-treated mice. Data are the mean ± S.E.M. Significance: * p < 0.05, ** p < 0.01, *** p < 0.001 vs. vehicle-treated db/db group.

4. Discussion

Dysregulation of the pathways involved in adipogenesis, lipid metabolism, and energy homeostasis can lead to the development of obesity, hepatic steatosis, diabetes, and dyslipidemia. The transcription factors PPARγ and CCAAT/enhancer-binding protein-α (C/EBPα) play a crucial role during adipogenesis. In the later stages of terminal differentiation, proteins such as adipocyte-specific fatty acid-binding protein (aP2), adiponectin, and leptin are expressed. A fine balance between adipocyte hypertrophy and adipogenesis exists to prevent the formation of dysfunctional adipose tissue, since large cells are more likely to be insulin-resistant and, therefore, can influence adipose tissue metabolism.

Adipose tissue, as a metabolic and endocrine organ, plays critical roles in the regulation of energy balance, lipid metabolism, and insulin action. Obesity is a major public health problem involving increased risks of diabetes and cardiovascular disease in many countries. Adipocytes have been emerging as a potential pharmacological target for obesity, diabetes, and cardiovascular diseases (24-26). Numerous studies have demonstrated that adipocyte differentiation and the amount of fat accumulation are associated with the occurrence and development of obesity. The findings of this study show that Kangen-karyu plays...
a significant role in the regulation of energy and lipid metabolism. Our results show that Kangen-karyu significantly inhibited adipocyte differentiation and lipid accumulation. Kangen-karyu significantly reduced TG accumulation, which indicates that it inhibited adipogenesis during adipocyte differentiation, and may have potential anti-dyslipidemia effects.

The differentiation of preadipocytes into adipocytes is regulated by the coordinated expression of various transcription factors, and the induction of metabolic pathways related to lipid metabolism induces the expression of several adipocyte-specific genes like PPARγ, SREBP-1c, and FAS (27). In addition, lipid homeostasis is regulated by a family of membrane-bound transcription factors called SREBPs (28). SREBP-1 is a key transcription factor that nutritionally regulates the hepatic gene expression of lipogenic enzymes and TG deposition in the liver (29). In the present study, Kangen-karyu significantly down-regulated the mRNA levels of PPARγ, SREBP-1c, and FAS, and the protein levels of aP2 and PPARγ in mature adipocytes. These results suggest that Kangen-karyu inhibited adipocyte differentiation and adipogenesis by affecting the transcriptional factor cascade upstream of PPARγ, SREBP-1c, FAS, and aP2, possibly resulting in the inhibition of lipid accumulation by inhibiting adipogenesis.

As an experimental model of dyslipidemia-associated type 2 diabetes mellitus, db/db mice are widely used and well-established (19,30). C57BLKS/J db/db mice develop diabetes due to mutation of the mouse diabetes (db) gene that encodes a receptor for leptin. The lack of leptin-receptor signaling results in increased food intake in combination with a phenotype of reduced energy expenditure, reminiscent of the neuroendocrine starvation response (31). Consequently, the homozygotes (db/db) after birth show unrepressed
eating behavior, become obese, and, by 3-6 months after birth, develop severe insulin resistance associated with hyperinsulinemia, hyperglycemia, and hypertriglyceridemia. Therefore, in this study, we investigated whether Kangen-karyu ameliorates metabolic disorders including hyperlipidemia, using well-established db/db type 2 diabetic mice.

The effects of Kangen-karyu on serum lipid levels such as TG, total cholesterol, HDL cholesterol, LDL/VLDL cholesterol, and NEFA were examined. We found that db/db mice showed hyperlipidemia. However, the administration of Kangen-karyu reduced hyperlipidemia through lowering TG, LDL/VLDL cholesterol, and NEFA. Also, to investigate the effects of Kangen-karyu on hepatic damage induced by abnormal lipid synthesis, the lipid contents in the liver of db/db mice were also examined. The hepatic content of TG was significantly decreased by the administration of Kangen-karyu. These results mean that Kangen-karyu may inhibit fat deposit or lipid output to blood with the regulation of lipid metabolism such as TG synthesis in type 2 diabetes.

Up-regulation of SREBP-1 was reported in leptin-resistant mice, such as ob/ob mice and FVB db/db mice (32,33). In this study, the increase in hepatic SREBP-1 in db/db mice was down-regulated by the administration of Kangen-karyu. This was probably related to the inhibition of hepatic TG accumulations. Furthermore, PPARs, with three isoforms (α, δ, and γ), are also involved in the long-term regulation of lipid metabolism, and their activity is modulated by endogenous lipid-derived ligands. When PPARs is activated, it promotes fatty acid oxidation, ketone body synthesis, and glucose sparing (34). In our study, hepatic PPARα was decreased in db/db mice; it was increased slightly, but not significantly, by Kangen-karyu administration. However, we found that Kangen-karyu exhibits a significant effect on regulation of SREBP-1. These results suggest that Kangen-karyu has an ameliorating effect on dyslipidemia in type 2 diabetic mice through the regulation of impaired hepatic SREBPs.

It is well known that SREBP-1 primarily controls genes involved in fatty acid synthesis (29). These include the genes for ACC and FAS in the fatty acid synthesis pathway (35). Type 2 diabetes is associated with increased de novo lipogenesis, decreased plasma fatty acid oxidation, and increased fatty acid flux from peripheral tissues to the liver (36). Therefore, we examined the effect of Kangen-karyu on regulating lipogenic enzyme genes such as ACC and FAS involved in fatty acid synthesis in the db/db mice liver using a real-time quantitative PCR technique. Our results strongly suggest that Kangen-karyu mediates the TG-lowering action by reducing the expression of ACC and FAS, thereby inhibiting fatty acid synthesis in type 2 diabetic mice.

Another finding noted in this study was that Kangen-karyu treatment improved impaired liver function in type 2 diabetic mice. Elevated serum levels of ALT and AST usually indicate hepatocyte damage (37). In db/db mice, serum ALT and AST were notably increased, but Kangen-karyu treatment showed a tendency to reduce these parameters, suggesting that Kangen-karyu might play an important role in improving liver function.

Thiazolidinediones and fibrate drugs are the most commonly used medications for type 2 diabetes mellitus, hyperlipidemia, and insulin resistance. They bind to and activate PPARs, which results in the upregulation of several genes involved in glucose and lipid metabolism (38). PPARs are currently viewed as potential therapeutic targets for the treatment of diabetes and dyslipidemia. PPARγ, predominantly expressed in adipose tissue and macrophages (39), affects genes involved in lipid synthesis and storage, and glucose homeostasis. PPARγ agonists, such as thiazolidinediones, control lipid metabolism and insulin sensitivity. However, several concerns such as body weight gain associated with an excess increase of fat mass arise in type 2 diabetes mellitus patients (40). Accumulating evidence indicates that the activation of PPARα stimulates lipid consumption by enhancing the expression of fatty acid oxidation genes, resulting in the amelioration of hyperlipidemia (41). PPARα agonists, such as fenofibrate used for the treatment of hyperlipidemia and reducing cardiovascular disease, have a potent effect on reducing plasma TG (42). Because of these distinct metabolic effects of PPARα and PPARγ agonists on insulin sensitivity and lipid metabolism, new drug development has focused on dual PPARs which possess PPARγ as well as PPARα activity. In this study, we initially assessed the protective effects of Kangen-karyu against type 2 diabetes by investigating specific markers in the serum and hepatic tissue of db/db mice, thereby highlighting Kangen-karyu as a promising anti-lipotoxic agent for type 2 diabetes.
