Physical and electrochemical properties of 1-ethyl-3-methylimidazolium ionic liquids of mixed anions, (FH)$_n$F$^-$, BF$_4^-$, and N(SO$_2$CF$_3$)$_2$ have been investigated. Molar volume shows almost linear behavior, whereas molar conductivity is decreased by mixing for the systems involving (FH)$_2$F$^-$ due to the enhancement of ion association in spite of the decrease in viscosity. The currents at the anode and cathode limits in the cyclic voltamogram of EMIm(FH)$_2$F decreases in the molar ratio of (FH)$_2$F$^-$ suggesting the involvement of (FH)$_2$F$^-$ for both electrode reactions. Electrochemical stability of the BF$_4^-$-TFSA mixture is unchanged by mixing.

Key Words: Ionic Liquid, Molten Salt, Mixed Ionic Liquids, Conductivity

1 Introduction

Room temperature ionic liquids (RTILs) are now widely studied as potential electrolytes for energy storage devices and plating, as well as media for extraction and separation processes, organic syntheses, and catalysis. Most imidazolium based RTILs are versatile and widely used due to their favorable characteristics such as low vapor pressure, wide liquid-phase temperature range, nonflammability, and high electrochemical stability. Physical properties of RTILs are changed by the combination of cationic and anionic structures. The tetrafluoroborate (BF$_4^-$) and bis(trifluoromethylsulfonyl) amide (N(SO$_2$CF$_3$)$_2$- or TFSA$^-$) anions are most widely used for syntheses of RTILs owing to their ability to form low melting salts with high conductivity. Fluorohydrogenate anion ((FH)$_n$F$^-$) also forms RTILs combined with a variety of heterocyclic ammonium cations, exhibiting remarkably high ionic conductivities. The vacuum-stable HF composition, $n$, for (FH)$_n$F$^-$ in the fluorohydrogenate RTILs based on the heterocyclic ammonium cations depends on the temperature, giving $n = 2.3$ at 25°C regardless of the cationic structure. The anions of the vacuum stable fluorohydrogenate RTILs at 25°C are regarded as a mixture of (FH)$_2$F$^-$ and (FH)$_3$F$^-$. In previous reports, mixing of RTILs was examined for several systems to improve the physical or chemical properties as electrolytes. This communication reports the physical and electrochemical properties of 1-ethyl-3-methylimidazolium (EMIm) ionic liquids of mixed anions, (FH)$_2$F$^-$, BF$_4^-$, and N(SO$_2$CF$_3$)$_2$.

2 Experimental

All the nonvolatile materials were handled in the dry Ar atmosphere of a glovebox. Room temperature ionic liquids, EMIm(FH)$_2$F$^-$ and EMImTFSA$^-$ were prepared according to the literature method. The tetrafluoroborate salt, EMImBF$_4$, was used as purchased (Kanto Kagaku Co., Inc.). Physical and electrochemical properties were measured as previously reported.

3 Results and Discussion

Physical properties of neat EMIm(FH)$_2$F, EMImBF$_4$, and EMImTFSA are listed in Table 1. The values obtained for EMImBF$_4$ and EMImTFSA agree well with those previously reported. Physical properties of EMIm ionic liquids of the mixed anions are shown in Fig. 1.

1.1 Density and molar volume

Density of the (FH)$_2$F-BF$_4$ system shows a linear relationship with $x$(FH)$_2$F, whereas those of the other two systems involving TFSA$^-$ show convex curvatures. Since the formula weight of EMImTFSA (391.3) is significantly larger than those of EMIm(FH)$_2$F (176.2) and EMImBF$_4$ (198.0), the contribution of EMImTFSA to the weight in the mixture is larger than the other salts, resulting in the increase in the apparent density with respect to the

molar ratio. The almost linear relationship is obtained in molar volume for all the mixtures, where the deviation observed for the (FH)$_2$F-BF$_4$ system is within error. This observation indicates that there is little volume change by mixing these ionic liquids, in other words, the volume which each ion occupies in the neat ionic liquid is preserved in the mixture.

3.2 Conductivity, molar conductivity, and viscosity

In all the three systems, both conductivities and molar conductivities exhibit concave curvatures by mixing the anions. The largest drop of the conductivity was observed for the TFSA-(FH)$_2$F system, where the conductivity of the 5050 mixture is only 42% of the estimated value from the neat RTILs. According to the previous study, the high conductivity for fluorohydrogenate RTILs is explained by their low viscosity, leading to the large diffusion coefficients of both the cation and anion compared to the ions in other RTILs although the anion moves faster than the cation.\textsuperscript{10} The decrease of the conductivity by mixing BF$_4^−$ and TFSA$^−$ is explained by the increase in viscosity as the viscosity shows the corresponding convex curvature. In the cases of the other two systems involving (FH)$_2$F$^−$, the association of the ions, that is, formation of ion pair or aggregate, is significantly enhanced by mixing the anions, since the viscosity shows concave curvatures violating Walden’s rule.\textsuperscript{7,8,12} It was reported that the molar conductivity for the EMImOSO$_2$CF$_3$-EMImTFSA system is enhanced by mixing the anions, showing a remarkably convex curvature,\textsuperscript{13} whereas such behavior was not observed for the present cases.

3.3 Thermal properties

Phase behavior of the mixed ionic liquids was studied by differential scanning calorimetry (DSC) in a Ni cell under a dry N$_2$ atmosphere at the scan rate of 10 K min$^{-1}$.

Both EMIm(FH)$_2$F and EMImBF$_4$ are super-cooled to form a glass phase in the cooling process, followed by glass transition point, crystallization, and melting in the heating process.\textsuperscript{7,8} The (FH)$_2$F-BF$_4$ mixture does not show any exo- or endothermic peak for the entire composition range, suggesting the stable super-cooled state. Although EMImTFSA showed an exothermic peak of crystallization in the cooling process followed by the melting in the heating process, the BF$_4^−$TFSA mixture does not show any exo- or endothermic peak for the entire composition range. These observations suggest
that BF₄⁻ facilitates the formation of the super-cooled state and prevent the system from crystallizing. As shown in Fig. 2, the (HF)₂₃F-TFSA mixture show both glass transition point and melting point in any composition. Since the mixture with a high ratio of EMIm(FH)₂₃F did not show a clear peak, the slow scan rate (2 K min⁻¹) was applied. The glass transition point gradually decreases with increase in the molar ratio of (HF)₂₃F⁻ in the range of 0 ≤ x(FH)₂₃F ≤ 0.6 and becomes almost constant in the range of 0.6 ≤ x(FH)₂₃F ≤ 1.0. The eutectic point EMIm(FH)₂₃F-EMImTFSA was determined to be 203 K at the composition of EMIm(FH)₂₃F : EMImTFSA = 90 : 10. The abrupt drop in melting point between 0.7 ≤ x(FH)₂₃F ≤ 0.8 may arise from a significant structural change in this region.

Thermal decomposition was examined by thermogravimetric analysis (TGA) in a Ni cell under a dry N₂ atmosphere at the scan rate of 10 K min⁻¹. The neat EMIm(FH)₂₃F slowly loses HF at elevated temperatures and decomposes around 550 K, whereas EMImBF₄ and EMImTFSA have higher thermal stabilities up to about 650 K and 700 K, respectively. Thermogravimetric analysis revealed that thermal decomposition of the component in the (FH)₂₃F-BF₄ or TFSA-(FH)₂₃F ionic liquid mixture occurs sequentially, giving two stages in the curve at the temperature corresponding to the decomposition of EMIm(FH)₂₃F and that of EMImBF₄ or EMImTFSA. The BF₄⁻TFSA system showed a gradual weight loss at and above the decomposition temperature of EMImBF₄.

3.4 Electrochemical stability

Electrochemical stability was examined by cyclic voltammetry using a glassy carbon electrode at the scan rate of 5 mV s⁻¹. Neat EMImBF₄ or EMImTFSA shows a similar electrochemical stability with the cathode limit of −2.5 V vs. Fe²⁺/Fe and anode limit of +2.1 V vs. Fe²⁺/Fe. Mixing of these two RTILs do not change the electrochemical stability in any ratio. Cyclic voltammogram of EMIm(FH)₂₃F-EMImBF₄ is shown in Fig. 3. The anode limit of neat EMIm(FH)₂₃F is +1 V vs. Fe⁺/Fe, which is probably ascribed to the oxidation of the cation accompanied by fluorination according to the previous study for neat liquids. The reaction of the cathode limit is considered to be the reduction of (HF)₂₃F⁻ to H₂ evolution. Although the potential of H₂ evolution depends on the electrode material, it is −1.8 V vs. Fe⁺/Fe on a glassy carbon electrode. In the mixed RTILs, the currents at the anode and cathode limits observed for EMIm(FH)₂₃F are decreased with decrease in molar ratio of (HF)₂₃F⁻, suggesting the involvement of (HF)₂₃F⁻ in both the limits. The cyclic voltammogram of the EMIm(FH)₂₃F-EMImTFSA mixture is essentially the same as that of EMIm(FH)₂₃F-EMImBF₄, although the peak current density is slightly different.
