Abstract. The octanoyl modification of ghrelin by ghrelin O-acyltransferase (GOAT) is essential for exerting its physiologic actions. Since exogenous acylated-ghrelin has shown to stimulate food intake in humans and rodents, GOAT has been regarded as a promising target for modulating appetite, thereby treating obesity and diabetes. However, GOAT-knockout (KO) mice have been reported to show no meaningful body weight reduction, when fed a high-fat diet. In this study, we sought to determine whether GOAT has a role in the regulation of body weight and food intake when fed a dietary sucrose. We found that GOAT KO mice showed significantly reduced food intake and marked resistance to obesity, when fed a high-fat + high-sucrose diet. In addition, GOAT KO mice fed a medium-chain triglyceride (MCT) + high-sucrose diet showed a marked resistance to obesity and reduced feed efficiency. These results suggest that blockade of acylated-ghrelin production offers therapeutic potential for obesity caused by overconsumption of palatable food.

Key words: Ghrelin O-acyltransferase, Acylated-ghrelin, High-sucrose diet

Materials and Methods

Animals and housing

GOAT-deficient mice were generated by Shionogi & Co., Ltd as described previously [10]. The mice were given free access to water and housed in individual cages in a temperature-controlled environment at 20 to 23°C on a 12-hour light/dark cycle. All experiments were conducted in a facility at Shionogi Pharmaceutical Research Center (Osaka, Japan) accredited by the Association for Assessment and Accreditation of Laboratory Animal Care International (AAALAC). All experimental protocols were approved by the Shionogi Pharmaceutical Research Center Institutional Animal Care and Use Committee.
**Body weight and food intake**

Seven-week-old WT and GOAT KO mice were given free access to water and one of the diets, a high-fat diet (D12492), a high-fat + high-sucrose diet (D12445), an MCT diet (D12331), and an MCT + high-sucrose diet (D12327), and body weight and food intake were monitored once a week for 12 weeks. Feed efficiency was determined by body weight gain for 12 weeks (g) divided by cumulative energy intake for 12 weeks (kcal).

**Results and Discussion**

Consistent with the previous report [7, 8], when fed a high-fat diet, GOAT KO mice showed comparable body weight gain, food intake, and feed efficiency to WT mice (Fig. 1). On the other hand, when fed a high-fat + high-sucrose diet, GOAT KO mice showed a significant reduction in food intake and body weight with no change in feed efficiency compared to WT mice. These results suggest that ghrelin/GOAT system is involved in the overconsumption of sugar-sweetened foods associated with body weight gain in WT mice. In addition, when fed an MCT diet, GOAT KO mice showed a slight reduction in food intake and body weight with no change in feed efficiency compared to WT mice. Since the ingestion of MCT diet has been indicated to increase the blood levels of AG [12], it might be possible to consider that activation of ghrelin/GOAT system by feeding an MCT diet may contribute to food intake and weight gain in WT mice. Interestingly, when fed an MCT + high-sucrose diet, GOAT KO mice showed a remarkable reduction of food intake and body weight as well as reduced feed efficiency compared to WT mice, which can be explained by the previous finding that GOAT KO mice fed an MCT + high-sucrose diet had a significant increase in whole-body energy expenditure along with decreased energy intake [10]. Further experiments are needed to investigate the difference of physiological role of AG in systemic energy homeostasis between an MCT + high-sucrose diet and other diets.

**Conclusions**

Our findings demonstrate that endogenous AG generated by GOAT system can promote the consumption of high-calorie food, especially containing high-calorie food.
Ghrelin and sucrose intake

amounts of sucrose, leading to a body weight gain. Recently, it has been reported that increasing consumption of sugar-sweetened beverages are associated with overweight and obesity [13], and a newly updated guideline from the World Health Organization (WHO) strongly recommends reducing the intake of free sugars such as sucrose and fructose [14]. Taking into consideration social demands to cut down on sugar intake, inhibiting GOAT activity may provide a therapeutic benefit in patients with obesity and type-2 diabetes.
