Papillary Muscle Hypertrophy in Chronic Rheumatic Mitral Valve Stenosis
A Clinicopathologic Study

Abdolhamid Sheikzadeh, M.D.,* Parviz Ghaboosi, M.D.,* and Iraj Nazarian, M.D., F.C.A.P.**

SUMMARY
A quantitative pathologic study was performed on papillary muscles in 15 cases of chronic rheumatic mitral stenosis. The papillary muscles were grossly hypertrophied as compared with papillary muscles in 10 normal specimens. Hypertrophy of papillary muscles was associated with pronounced fibrosis. Angiographically, these hearts were remarkable in small left ventricular cavity with almost complete cavity elimination at end systole. Left ventricular wall dyskinesia was also present. It is probable that derangement of the mitral valve structure due to rheumatic process leads to more stress on the supporting elements, thus resulting in papillary muscle hypertrophy.

Additional Indexing Words:
Left ventricular cavity elimination Chest pain Mitral valve apparatus

CHARACTERISTICS of papillary muscles (PMs) have been the subject of several reports dealing with mitral valve prolapse1) and nonobstructive cardiomyopathy.2) However, as far as we know, no detailed morphometric study has been reported regarding the PMs in rheumatic mitral stenosis (MS). The purpose of this report is the presentation of the clinical, hemodynamic, angiographic, and pathologic aspects of a selected group of patients with chronic rheumatic MS with particular reference to PMs. Attempt will be made to correlate the anatomic and clinical findings.
MATERIALS AND METHODS

In a retrospective review of 200 left ventricular angiograms in adult patients with chronic rheumatic MS, 48 cases were found remarkable in relatively small left ventricular cavity with almost complete end-systolic cavity elimination due to what appeared to be PM hypertrophy. Review of these 48 cases showed that in 15 cases the mitral valve as well as the entire length of the PMs were available at the pathology museum. In the remaining 33 cases either the patients had not undergone operation at this center or the surgical specimen was not adequate for morphometric study developed for this project. In all 15 cases the diagnosis of rheumatic etiology was documented by previous history, laboratory data and surgical findings. The age of the patients ranged between 15 and 50 (mean 29.5) years. In these 15 cases left ventricular angiograms obtained in right anterior oblique position were critically reviewed with particular attention to the mitral valve ring, left ventricular cavity and left ventricular wall contraction pattern.

Echocardiograms of 15 cases were also analyzed qualitatively and quantitatively. Pathologic study of the specimens consisted of 3 parts:

A. Gross qualitative examination.

B. Qualitative microscopic examination of cross sections from the 3 levels described under “C” using trichrome and hematoxylin and eosin staining.

C. Morphometric study. The circumferences of the PMs were measured at 3 levels ie at the tip, 5 mm below the tip and 10 mm below the tip. The tip of the PM was defined visually at the line of junction of the mitral valve cusp and the PM. The circumferences at the 3 cross sectional levels were calculated using the formula \( C = \pi \times 2R \), where 2R represented the arithmetic mean of 4 transverse diameters measured at intervals of 45 degree (Fig. 1), and C represented circumference.

For comparison of the PM measurements, 10 adult heart specimens were chosen which had grossly normal mitral apparatus. Eight hearts were obtained from patients who expired because of coronary artery disease, whereas in 2 cases systemic hypertension was present. The same morphometric method was applied to the PMs of these hearts.

\[
2R = \frac{AB \cdot CD \cdot EF \cdot GH}{4}
\]

Fig. 1. On the left hand the 3 levels used for measurement are shown. On the right hand the mean diameter of the PM is measured by averaging 4 values obtained at intervals of 45 degree.
RESULTS

The clinical findings in the 15 patients are summarized in Table I. The remarkable aspects were severe physical disability and high frequency of chest pain.

Review of the echocardiographic findings are summarized in Table II. Remarkable findings were a very small left ventricular end-diastolic dimen-
sion and a peculiar unexplained picture depicted by a high positioned echo beam (Fig. 2).

Hemodynamic values are summarized in Table III. The results of angiocardio- graphic evaluation are shown in Table IV. Remarkable findings were reduced mitral valve ring motion in 9 of 15 patients. Anterior and posterior left ventricular wall dyskinesia and early relaxation were present in all (Fig. 3). The results of PM measurements are shown in Table V. Note that at all 3 levels the circumference of the PMs is significantly greater than that of normal PMs.

Gross examination of the surgically removed mitral valves, disclosed a significant hypertrophy of both papillary muscles with thick, rigid, and immo-

Fig. 5. Photomicrograph of a cross-section of the papillary muscle in a case of rheumatic mitral stenosis. The section was obtained at 1 cm level.
bile valve cusps. The most striking feature was the absorption and impac-
tion of the chordae tendineae and PMs into the cusps leaving no appreciable
chordae tendineae (Fig. 4). Histological sections of the PMs revealed tremen-
dous interstitial fibrosis, especially in areas close to the tip (Fig. 5).

**DISCUSSION**

Hypertrophy of the PMs has been described in mitral valve prolapse\(^1\) as
well as nonobstructive cardiomyopathy.\(^2\) Jersaty reported prominence of
the papillary muscles associated with excessive emptying of the left ventricu-
lar cavity, particularly the apex in most patients with prolapse of mitral valve.
Previous angiographic studies have documented severe distortion of the mi-
tral valve apparatus, including fusion of the PMs and the leaflets, and enlarg-
ed papillary muscles.\(^3\) Boucek et al reported hypertrophy of the papillary
muscles in patients with MS,\(^4\) and Akins et al described the angiographic fea-
tures of distorted mitral apparatus in this condition.\(^5\) However besides these
and a cursory remark on PM hypertrophy in rheumatic MS\(^6\) we have not
come across any quantitative study of the PMs in this disorder. In this study
we documented that PM hypertrophy was present and was probably respon-
sible for angiographic finding of end-systolic left ventricular cavity elimina-
tion. Thus in all 15 specimens the PMs were grossly hypertrophied as oposed
to normal, and led to small left ventricular end-systolic dimension. This is
in contrast to previous reports which showed end-systolic volumes signifi-
cantly larger in MS patients than in normal controls.\(^7\) Abnormal contraction
pattern noted in our patients has been reported before.\(^7\)–\(^10\) The reason for
occurrence of PM hypertrophy is not established. Cobb\(^11\) and Barlow\(^12\) have
reported that the mitral apparatus is so designed that during normal cardiac
function, there is minimum stress on both chordae tendineae and papillary
muscles. This is due to: 1-keystone effect during systole and 2-special geometry
of the mitral valve. Moreover studies of chordae tendineae and PM ten-
sion have indicated that tension is diminished in these structures after mitral
valve opening. Thus severing chordae tendineae and papillary muscles in-
creased tension in the remaining chordae tendineae and PMs during systole.
Thus one can speculate that because of severe distortion of the architecture of
the mitral valve and its supporting elements, these stress reducing mechanisms
are eliminated. Increased stress on the PMs leads to hypertrophy. Another
finding in this study is the remarkably high frequency of chest pain in pati-
ents with severe MS. Papillary muscles, being the last portions of the heart
to be perfused by the coronary arterial blood, are very sensitive to myocardial
ischemia.\(^13\) Severe hypertrophy of the papillary muscle with anatomically
demonstrable fibrosis may be due to ischemia of PMs and may explain the frequency of chest pain in these patients.
