Infective aortitis, though uncommon, must be recognized as an etiology of fever of patients with advanced atherosclerosis, and early treatment can improve its survival.

A 68-year-old woman was admitted to our hospital because of fever and abdominal pain. She had had a history of rheumatoid arthritis treated with steroid for ten years. On admission, the white blood cell count was 18,800/µl and C-reactive protein level was 25.8 mg/dl. Several blood cultures for bacteria were negative. An abdominal CT revealed a periaortic abscess with air density spots (Fig. 1A). She was diagnosed with infective aortitis and treated with antibiotics. On the 13th hospital day, an enhanced CT demonstrated an increase in periaortic abscess with extravasation of contrast medium (Fig. 1B). Impending rupture of infected aneurysm was clinically diagnosed, and she underwent emergency operation at another hospital. Air density spots in periaortic abscess are useful findings for early diagnosis of infective aortitis.
