The patient presented leg edema and erythema on her left calf.

A T2-weighted MRI scan. A sagittal scan of the left leg showed a high-density lesion in the popliteal space, indicating the presence of a Baker’s cyst.

A Baker’s cyst is an abnormal collection of fluid on the back of the knee. The clinical presentation of symptomatic Baker’s cyst is similar to thrombophlebitis. This is termed pseudothrombophlebitis syndrome (1).

We advised bed rest with leg elevation. She recovered spontaneously within a few weeks.
