Key words: colon tumor, metastasis, renal cell carcinoma

A 74-year-old man was admitted to our hospital with dyspnea. A chest X-ray showed multiple lesions in both lung fields and left pleural effusion. Computed tomography revealed a left renal tumor 35 mm in diameter with enhancement (Picture a) and multiple metastatic lesions of both lungs and bones. Colonoscopy revealed only a submucosal tumor-like tumor measuring 4 mm in diameter in the transverse colon (Picture b). Examination of biopsy specimens from the tumor revealed features characteristic of renal cell carcinoma (RCC) (Picture c). Therefore, the patient was diagnosed as having RCC with metastasis to the colon.

There have been few reports of metastatic colon tumors from RCCs. In the present case, we detected a rare metastatic tumor in the colon arising from RCC. The pathway of metastasis to the colon is still not well known.
