Key words: aneurysm, the superior mesenteric artery, ileus

(Intern Med 51: 3301-3302, 2012)
(DOI: 10.2169/internalmedicine.51.7650)

A 49-year-old man, diagnosed with annuloaortic ectasia and treated by surgery three years earlier, was admitted to the hospital with abdominal pain.

He presented with vital signs indicating shock and abdominal pain. Enhanced computed tomography (CT) of the abdomen revealed ascites and an aneurysm of the superior mesenteric artery (Picture A). An impending rupture due to peritonitis and aneurismal coiling was observed in an emergency angiogram (Picture B). Although his condition was good and he was initially discharged from the hospital, he returned with nausea and abdominal pain. CT showed a dilated small intestine and a mass in the stomach (Picture C). The ileus was thought to be caused by relative ischemia due to aneurismal coiling and surgery was performed to remove the ischemic portion of the small intestine (1).

The authors state that they have no Conflict of Interest (COI).
