A 50-year-old woman presented with epigastralgia. A blood examination showed liver dysfunction. The IgG4 level was within the normal limits. CT (Picture 1) revealed a thickened wall of the extrahepatic bile duct. ERCP (Picture 2) showed paired extrahepatic bile ducts with a stricture. Intraductal ultrasonography (IDUS, Picture 3) demonstrated a regularly thickened wall of each duct with a layer structure. A biopsy and cytology of the stricture did not show malignancy. A nasobiliary tube was placed in the right intrahepatic bile duct through one of the paired bile ducts.

ducts. Oral steroids were administered for two weeks, and the stricture of the extrahepatic bile duct resolved (Picture 4).

Our case is rare and was classified as a type V duplication of the extrahepatic bile duct (1). If the serum IgG4 level is elevated, making the diagnosis of bile duct stricture as benign is not difficult. In patients with a normal IgG4 level, steroid administration can contribute to the diagnosis.

The authors state that they have no Conflict of Interest (COI).
