Abstract

A 68-year-old man on peritoneal dialysis (PD) was hospitalized with the clinical picture of peritonitis. The patient was diagnosed with peritonitis caused by nontuberculous mycobacteria (NTM) according to positive Ziehl-Neelsen staining and negative *Mycobacterium tuberculosis* polymerase chain reaction results. Oral levofloxacin and clarithromycin, and later intraperitoneal imipenem were started. According to the anti-NTM susceptibility test results, oral minocycline was administered. The patient was treated for 6 months. He recovered without PD catheter removal; thus, PD was successfully continued. A genetic analysis identified the isolate as *Mycobacterium iranicum*. This is the first report of PD-related peritonitis caused by *M. iranicum*.

Key words: *Mycobacterium iranicum*, peritoneal dialysis, peritonitis

Introduction

Peritoneal dialysis (PD)-related peritonitis is a major complication of PD therapy, and it is one of the most common reasons for PD withdrawal (1). When PD-associated peritonitis is culture negative, persistent or recurrent, or unresponsive to standard empirical antibiotic treatment, nontuberculous mycobacteria (NTM) should be suspected. We herein report a case of PD peritonitis caused by *Mycobacterium iranicum*, a rapidly growing mycobacterium that has not previously been linked with peritonitis. We successfully treated *M. iranicum* peritonitis without removing the PD catheter and discontinuing PD.

Case Report

A 68-year-old man with diabetic nephropathy had undergone PD for 7 months. The PD bag exchange protocol was 1 L exchanges of a 1.5 % glucose-based solution (Dianeal-N PD-2 peritoneal dialysis solution with 1.5% dextrose; Baxter) four times daily. To change the PD fluid bags, the patient used a sterile connecting ultraviolet flash device. He was not treated with any immunosuppressive therapies, and a serological test for human immunodeficiency virus (HIV) was negative. He had no history of peritonitis and had not taken any antibiotics for 6 months. Interestingly, he frequently cultivated flowers.

Upon visiting our hospital, the patient presented with cloudy peritoneal fluid. Aside from this, he did not have any symptoms such as abdominal pain or a fever. His vital signs were as follows: blood pressure, 138/81 mmHg; pulse, 89/min; and temperature, 36.6°C. On physical examination, no abdominal tenderness was found, and the peritoneal catheter exit site was clear. The blood laboratory data were as follows: total WBC count, 8,100 cells/mm³ with 69.1% neutrophils, 17.6% lymphocytes, 9.0% monocytes, 3.7% eosinophils, and 0.6% basophils; blood urea, 41.1 mg/dL; plasma creatinine, 6.99 mg/dL; C-reactive protein, 1.9 mg/dL; and HbA1c, 5.4%. The WBC count of the peritoneal fluid was 1,200 cells/mm³ with 55% neutrophils and 45% lymphocytes.

On first presentation, he was hospitalized. An intraperitoneal infusion of cefazolin and ceftazidime was administered. On day 2, the dialysate that was obtained at admission showed a positive Ziehl-Neelsen stain and negative Myco-

bacterium tuberculosis polymerase chain reaction (PCR) results. The patient was diagnosed with PD-related peritonitis caused by NTM. Oral levofloxacin (500 mg every second day) and clarithromycin (400 mg daily) were administered. On day 5, the WBC count of the peritoneal fluid increased to 13,200 cells/mm$^3$; thus, the previous intraperitoneal antibiotics were discontinued. Subsequently, intraperitoneal imipenem (1,000 mg daily) was administered. On day 12, the peritoneal fluid became clear, and the WBC count of the peritoneal fluid decreased to 900 cells/mm$^3$. Drug minimal inhibitory concentrations (MICs) were determined using the broth microdilution method per the Clinical Laboratory and Standards Institute (CLSI) guidelines (2). The NTM was susceptible to amikacin, ciprofloxacin, clarithromycin, imipenem, and minocycline (Table). According to the susceptibility test results, intraperitoneal imipenem was discontinued, and oral minocycline (100 mg daily) was introduced on day 51. The WBC count of the peritoneal fluid decreased to <100 cells/mm$^3$, and the patient was discharged on day 55. After discharge, all three oral antibiotics were continued for 4 months. At the time of writing, 3 months after the cessation of therapy, the patient has continued PD without relapsing peritonitis.

Although, the dialysate showed a positive acid-fast culture on day 5, we were not able to identify the type of NTM. Further identification of the isolate was performed at the Research Institute of Tuberculosis, Japan Anti-tuberculosis Association on day 25. 16S rRNA and hsp65 sequencing were performed, and the results showed 100% and 99.2% sequence identity with M. iranicum, respectively, on day 38.

### Table. Results of Anti-rapidly Growing Nontuberculous Mycobacteria Susceptibility Testing of Mycobacterium iranicum Isolated from the Peritoneal Fluid. This was Enforced in Compliance with the CLSI-M24-A2 Guidelines.

MICs: minimal inhibitory concentrations

In summary, this is the first report of PD-related peritonitis caused by M. iranicum. At first presentation, we considered a potential mycobacterial infection and ordered a dialysate acid-fast culture. Therefore, we diagnosed the NTM infection early, and successfully treated the infection without catheter removal.
removing the PD catheter. The patient was allowed to continue PD.

The authors state that they have no Conflict of Interest (COI).
