Abstract:
The patient was a 76-year-old man who was treated with nivolumab due to recurrent gastric cancer. A blood examination revealed grade 3 alkaline phosphatase (ALP) elevation. A histopathological examination revealed marked portal infiltration, including eosinophils and CD4+ and CD8+ T lymphocytes, suggesting nivolumab-related cholangitis accompanied by the features of both an immune-related adverse event (irAE) and drug-induced liver injury (DILI) with allergic reaction. The patient’s ALP level immediately decreased after the administration of prednisolone. Although nivolumab-related cholangitis, a rare irAE, has been reported to be refractory to steroid therapy, patients with features of irAE and allergic DILI might immediately respond to prednisolone.

Key words: nivolumab-related cholangitis, prednisolone, eosinophils, immune-related adverse event, drug-induced liver injury

Introduction

Nivolumab, a human immunoglobulin G4 monoclonal antibody, inhibits the interaction between the programmed cell death-1 (PD-1) receptor and its ligands (PD-L1 and PD-L2) and restores antitumor immunity (1, 2). Based on evidence of its antitumor effects, nivolumab is approved for the treatment of various advanced malignancies, including melanoma (3), non-small cell lung cancer (NSCLC) (4), renal cell carcinoma (RCC) (5), squamous cell carcinoma of the head and neck (6), Hodgkin’s lymphoma (7), and gastric cancer (8).

Given that nivolumab is an immunomodulatory agent, specific immune-related adverse events (irAEs) caused by dysregulation of the host immune system occasionally occur during treatment (9). Typical irAEs in nivolumab-treated patients with NSCLC or gastric cancer include skin rash and diarrhea, which are reported to occur in 6.0-11.0% and 7.0-10.0% of patients, respectively (4, 8). The minor but important irAEs include endocrinopathies (4), pneumonitis (10), type 1 diabetes mellitus (11), and acute hepatitis (8, 12). Recently, nivolumab-related cholangitis has been reported as a rare irAE in patients with NSCLC and melanoma (13-17). In addition, the Ministry of Health, Labor and Welfare in Japan called for more research on nivolumab-related cholangitis, after 10 cases of cholangitis after administration of nivolumab were reported on July 5th, 2017. As previous reports suggested that nivolumab-related cholangitis is a serious irAE that shows a moderate to poor response to steroid therapy (13-17). Thus, patients could not often receive alternative chemotherapy.

We herein report a case of nivolumab-related cholangitis accompanied by features of both irAE and drug-induced liver injury (DILI) with allergic reaction in a patient with advanced gastric cancer. Interestingly, the patient showed an
immediate response to prednisolone and was able to receive alternative chemotherapy.

Case Report

The patient was a 76-year-old man who had undergone distal gastrectomy and lateral hepatectomy for advanced gastric cancer and liver metastasis, respectively, after neoadjuvant chemotherapy four years previously. A histopathological examination revealed HER2-negative well-differentiated tubular adenocarcinoma. He received adjuvant chemotherapy with S-1. However, 12 months later, abdominal lymph node metastases appeared, and he subsequently received other systemic chemotherapies. At three years after surgery, he was treated with nivolumab as the 4th-line chemotherapy. Although a physical examination showed no jaundice or abdominal symptoms, after the administration of 4 cycles of nivolumab, a blood examination revealed grade 3 alkaline phosphatase elevation (ALP: 2,427 U/L) and grade 2 gamma glutamyl transferase elevation (γGTP: 252 U/L). However, only mild elevation of the patient’s aspartate aminotransferase (AST: 69 U/L) and alanine transaminase (ALT: 68 U/L) levels was noted. Although computed tomography imaging revealed mild dilation of the extrahepatic bile duct, no dilation or obvious obstruction of the intrahepatic bile duct was noted. A blood examination revealed an increased eosinophil count (6.4%), no viral hepatitis infection (HAV, HBV, HCV, and HEV), and indications of previous CMV and EBV infection. The patient’s serum immunoglobulin G (IgG), IgG4, and IgM levels were normal. The patient was negative for anti-nuclear antibody, anti-mitochondrial antibody (AMA), AMA-M2, and anti-smooth muscle antibody. Because these blood abnormalities were not typical for hepatic irAE, the patient was treated with ursodeoxycholic acid (UDCA) as a liver support therapy, after which his serum AST and ALT levels decreased. However, his serum ALP and γGTP levels did not improve; thus, liver biopsy was performed. A histopathological examination of the liver biopsy specimens revealed marked portal infiltration of mixed inflammatory cells, including eosinophils (Fig. 1A and B), which was accompanied by mild interface hepatitis with the appearance of a few acidoxyphic bodies (Fig. 1B). Eosinophils had infiltrated the epithelial lining of the interlobular bile ducts (Fig. 1C), and cytokeratin 7 immunohistochemistry revealed a mild ductular reaction (Fig. 1D). Most infiltrating lymphocytes were CD3+ (data not shown), and included both CD4+ helper T cells and CD8+ suppressor T cells (Fig. 1E and F).

Because the histopathological findings indicated portal infiltration of mixed inflammatory cells and atypical acute hepatitis as an irAE, we initially suspected cholangitis due to biliary tract infection; thus, antibiotic treatment was initiated. However, the serum ALP and γGTP levels did not improve. Thus, the patient was diagnosed with nivolumab-related cholangitis with an irAE based on the histopathological findings of CD4+ and CD8+ T lymphocyte infiltration in the portal tract. In addition, the portal infiltration of eosinophils suggested DILI with allergic reaction. The oral admini-

B: Diffuse portal infiltration of mixed inflammatory cells with a predominance of eosinophils accompanied by mild interface hepatitis (arrow, acidophilic body). C: Infiltration of eosinophils within the epithelial linings of the intrahepatic bile ducts (arrows). D: Mild ductular reaction within the inflamed portal tract. E, F: Infiltration of both CD4+ helper T-cells and CD8+ suppressor T-cells in the portal tract. Hematoxylin and Eosin staining (A-C); immunohistochemical staining of CK7 (D), CD4 (E), and CD8 (F). CK, cytokeratin.
Although the initiation of steroid therapy (1-2 mg/kg) is recommended for patients with immune-related hepatitis (12), the appropriate dose is for patients with immune-related cholangitis is unclear. In addition, our patient was resistant to steroid treatment. Kawakami et al. reported that the early use of a sufficient quantity of immunosuppressive agents may be effective in terms of clinical improvement (14). In case 6, after increasing the dose of prednisolone from 1 mg/kg to 2 mg/kg, the patient’s biliary enzyme levels gradually improved. If irAEs are refractory to steroid therapy, other immunomodulatory medications, including mycophenolate mofetil, tacrolimus, and cyclosporine may be used (12); however, there are no reports regarding hepatitis or cholangitis treated with other immunomodulatory medications, with the exception of a patient who received antithymocyte globulin (19).

Discussion

In a phase I study of 296 patients with advanced solid tumors, including melanoma, NSCLC, RCC, prostate cancer, and colorectal cancer, increased ALT and ALP levels were noted in 4% and 1% of patients, respectively (2). The Checkmate 057 phase III study, which included 292 NSCLC patients revealed that the serum levels of ALT, ALP, and γGTP increased by 3%, 1%, and 1%, respectively (18). These data suggest that immune checkpoint inhibitor-related liver injury usually appears as a hepatitis pattern and that the cholangitis pattern is a rare irAE. With regard to cholangitis, only seven cases of nivolumab-related cholangitis in NSCLC and melanoma patients have been reported (Table 2) (13-17). In addition, nivolumab-induced cholangitis was only reported in 10 of 18,562 (0.05%) patients with metastatic melanoma, NSCLC, RCC, squamous cell carcinoma of the head and neck, or Hodgkin’s lymphoma, according to the post-marketing surveillance of the Ministry of Health, Labor and Welfare in Japan from 2014 to 2017 (16).

A previous report that analyzed 2 patients treated with prednisolone suggested that nivolumab-related cholangitis showed a moderate to poor response to steroids therapy (14). As Table 2 indicates, seven cases—including our own—were treated with steroids. With the exception of our case, all cases showed a moderate to poor response to steroid treatment, suggesting that nivolumab-related cholangitis was resistant to steroid treatment. Kawakami et al. reported that the early use of a sufficient quantity of immunosuppressive agents may be effective in terms of clinical improvement (14). In case 6, after increasing the dose of prednisolone from 1 mg/kg to 2 mg/kg, the patient’s biliary enzyme levels gradually improved. If irAEs are refractory to steroid therapy, other immunomodulatory medications, including mycophenolate mofetil, tacrolimus, and cyclosporine may be used (12); however, there are no reports regarding hepatitis or cholangitis treated with other immunomodulatory medications, with the exception of a patient who received antithymocyte globulin (19).
suffered from impaired glucose tolerance (fasting blood glucose level: 114-115 mg/dL and casual blood glucose level: 189-227 mg/dL); thus, a low dose of prednisolone (0.5 mg/kg) was administered. After the administration of a low dose of prednisolone, the patient’s biliary enzyme levels immediately decreased. Histopathological findings of CD4+ and CD8+ T lymphocyte infiltration into the portal tract were consistent with a pathological feature of irAE, as suggested by a previous report (14). In contrast, eosinophilic infiltration is a feature of an immunoallergic reaction, which is generally associated with a better prognosis in patients with DILI (20). Indeed, a blood examination revealed eosinophilia (≥6%), which is one of the diagnostic criteria for DILI with allergic reaction in Japan (21). These histological findings indicated that the present case had the features of both irAE and DILI with allergic reaction. Although the role of eosinophilia in the peripheral blood and liver is unclear, one possible reason why our patient immediately improved after treatment with a low-dose prednisolone is because the patient showed histopathological features of both irAE and DILI with allergic reaction. In contrast, the serum ALP levels gradually improved with both methylprednisolone and UDCA treatment in case 1. In addition, the first prednisolone treatment was not effective in case 5; however, the patient’s biliary enzyme levels gradually improved after additional UDCA treatment. These findings suggest that the administration of both steroids and UDCA may improve nivolumab-related cholangitis.

The marked infiltration of both CD4+ and CD8+ T lymphocytes in this case was a salient histopathological feature,
which is consistent with previous reports of nivolumab-related cholangitis with an irAE (13-17). However, previous reports have demonstrated that drug-induced cholangitis or eosinophilic cholangitis is associated with periporal mixed inflammatory infiltration including lymphocyte infiltration (22-24). Although the immunophenotypes of these lymphocytes have not been shown in these studies, CD4+ and CD8+ T lymphocytes could be recruited in such conditions. Thus, it should be noted that cholangitis due to irAE cannot be clearly distinguished from allergic cholangitis by pathological features alone.

Recently, a correlation between irAEs and anti-tumor effects was reported in patients with lung cancer and melanoma (25-27). In the present case, the patient’s CEA level did not increase during nivolumab treatment while the patient’s CEA level increased after the discontinuation of the drug. These findings might suggest the persistent efficacy of nivolumab treatment, thereby supporting the fact that irAE patients demonstrated a favorable efficacy for nivolumab treatment.

In conclusion, we reported a case of nivolumab-related cholangitis in a patient with recurrent gastric cancer who showed an immediate response to prednisolone therapy and who could receive alternative chemotherapy. Because it is important to evaluate and treat nivolumab-related cholangitis before resuming subsequent chemotherapy, prednisolone should be administered if a blood examination reveals eosinophilia and if the histopathological analysis of a liver biopsy specimen reveals eosinophils and CD4+ or CD8+ T lymphocyte infiltration.

The authors state that they have no Conflict of Interest (COI).
