Large Right Ventricular Myxoma in a 79-Year-Old Male

A 79-year-old male, admitted because of severe dyspnea on exertion, showed echocardiographic findings of a large tumor in the dilated right ventricle. The right ventricular outflow tract was nearly occluded by the tumor mass, and the mass was attached to the interventricular septum by a pedicle. The tumor removal operation was successful. The size of the tumor was 40 mm x 90 mm, and the weight 70 g. Microscopic findings showed typical myxomatous tissue with high cellularity, and no malignancy was observed. This is the oldest reported patient with right ventricular myxoma which was cured by operation. (Internal Medicine 35: 380-382, 1996)

Key words: right ventricular outflow tumor, pulmonic valvular occlusion, right heart failure

Case Report

Myxoma most typically develops in the atria, and rarely in the ventricles. Recently, we treated a rare case of large right ventricular myxoma in a 79-year-old male. He had the symptom of dyspnea on effort for several years, and was admitted to our hospital on October 26, 1990 due to worsening of that symptom. Physical findings showed regular pulsation of 130/min, and blood pressure of 102/64 mmHg in the supine position, but it was not possible to measure his blood pressure and pulsation in the sitting position. He had no lymphadenopathy or pretibial edema. Auscultation showed decreased second heart sound without murmur, normal vesicular sound with no rales. Abdomen was soft and flat without any mass palpable, or ascites. Laboratory findings showed the following: white blood cell count 6,800/mm³, hemoglobin 16.4 mg/dl, hematocrit 49.3%, platelet 9.3x10⁴/mm³, glutamic oxalacetic transaminase 103 U/l, glutamic pyruvic transaminase 123 U/l, lactic dehydrogenase 1,571 IU/l, creatinine phosphokinase 69 IU/l, creatinine 1.3 mg/dl, sodium 134 mEq/l, potassium 4.6 mEq/l, chloride 100 mEq/l. Analysis of arterial blood gas in the room air showed PO₂ of 65 Torr, PCO₂ of 27 Torr, and HCO₃ of 19 mEq/l. On electrocardiogram, normal sinus rhythm with complete right bundle branch block was observed. There was no abnormal finding on the chest X-ray picture. On the echocardiogram, a large tumor mass was seen in the dilated right ventricle, and the left ventricle showed a small deformed cavity (Fig. 1). The right ventricular outflow tract was nearly occluded by the tumor mass. The mass was attached to the interventricular septum by a pedicle; it was mobile inside the right ventricular outflow tract, moving toward the pulmonic valve in systole (Fig. 2). On the 10th hospital day, cardiac catheterization examination was done. The central venous pressure was 21 Torr, and the right ventricular pressure 66/8 Torr (end-diastolic pressure 22 Torr). Coronary angiography revealed no abnormality. Right ventriculography revealed a large defect in the outflow tract region (Fig. 3). Because of rapidly progressing liver dysfunction due to right heart failure, an emergency operation was done on the 12th hospital day. The right ventricular outflow tract was markedly swelled without contractility by the tumor mass, and the right atrium was dilated and hypertrophied, suggestive of pressure overload. After making an incision in the right atrium, a large tumor mass was seen along the right ventricular outflow tract, attached to the interventricular septum by a pedicle. The tumor was resected by carrying out an incision into the pulmonary artery trunk. The size of the tumor was 40 mm (diameter) x 90 mm (length), and the weight was 70 g (Fig. 4). Microscopic findings showed typical myxomatous tissue with high cellularity, and no malignancy was observed (Fig. 5). Since then, he has been followed on an outpatient basis in stable condition, without right heart failure or liver dysfunction.

Discussion

Primary cardiac tumor is relatively rare, and the proportion of the myxoma occupies more than half of the primary tumor
Large RV Myxoma in a 79-Year-Old Male

Cardiac myxoma always originates in the atria, and rarely in the ventricles (1–4). The typical clinical symptom of right ventricular myxoma is illustrated as dyspnea, chest pain, syncopal attack, and cyanosis (1, 3–5). This inability to measure the blood pressure in the sitting position may reflect the pulmonary valvular occlusion by the tumor mass (3, 5, 6). The present patient is the oldest reported case of right ventricular myxoma cured by operation (4, 5, 7). The tumor had grown gradually for a long time to nearly obstruct the right ventricular outflow tract (6), and was successfully and safely resected by operation. Therefore, it is important that resection of the right ventricular myxoma is achieved as quickly as possible even in an old patient such as this case, to prevent serious complications that can ensue in untreated patients (5, 8).
